Public Health Reports, published since 1878 under authority of an act of Congress of April 29 of that year, is issued monthly by the Public Health Service pursuant to the following authority: law: United States Code, title 42, sections 241, 245, 247; title 44, section 22. Use of funds for printing this publication approved by the Director of the Bureau of the Budget, August 24, 1957.

U.S. DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE

ARTHUR S. FLEMMING, *Secretary*

PUBLIC HEALTH SERVICE

LEROY E. BURNEY, *Surgeon General*

Described as a valuable administrative tool, a system of gathering statistics on health services is outlined in relation to health department programs.

Health Service Statistics Record System

DORIS L. DUXBURY

HEALTH departments are constantly coping with the problems of insufficient money and people to carry on their present programs; at the same time, the rapidly growing population is making demands for new and increased health services. Facts concerning past and present services to the current programs are sorely needed as a means of evaluating past services, redesigning current operations, and determining priorities for the future. How can we obtain these facts in a simple manner?

Most public health workers are already overburdened with recordkeeping, and we need to be very cautious about adding to this load. However, many of the present recordkeeping systems are designed to provide specific information regarding a certain program without thought of relating it to other information concerning the same program or to other programs.

The scope of public health services is continually broadening, and more and more disciplines are represented on the staffs of health departments. The result is that no one program is conducted solely by one organizational unit of the department, but rather through the co-

operative effort of many disciplines from several program units. For example, usually the tuberculosis services of a health department include the work of not only the tuberculosis division but also other divisions such as nursing, nutrition, education, social service, and environmental health. This interdependence of disciplines is increasing rather than decreasing, and as it increases so will the need increase for interrelated statistics. To collect service statistics from several units concerning a single program is both a necessity and a problem.

For some time, statisticians of the Michigan Department of Health had been disturbed by the lack of service statistics compiled by program and had recognized a need for a system to provide these data on a departmentwide basis regardless of organizational units. A new system began in the Michigan Department of Health the day the chief of the nutrition section came to the statistical methods section for help with the reporting system for her section. She commented that the daily reports were time consuming to tabulate, and once counted had little meaning for they could not be related to each other and, consequently, were of little value for program planning or evaluation. The nutrition section seemed a logical unit for a pilot study in the use of a new system. There were only five members on the staff, and they

Miss Duxbury is chief of the statistical methods section in the division of disease control, records, and statistics, of the Michigan Department of Health, Lansing.

were carrying on a type of program which provided service to practically all other major health department programs.

Basic Record

The first step toward establishing the new system was to determine the type of basic record to be used. It was recognized that it must be a simple one in order to obtain complete and accurate reporting. This, together with the availability of IBM tabulating equipment in the department, resulted in the selection of the IBM mark sense card, designed to be used as the basic record for collecting and tabulating the data (fig. 1).

The fieldworker carries with him a small supply of these cards and a special IBM electrographic pencil. He records the services he gives by means of a few pencil marks on these cards; one card is used per activity according to the codes, all of which are indicated on the front or back of the cards with the exception of the geographic area code. Thus, only one code needs to be carried by the worker and since many workers provide services within limited geographic areas, they soon become familiar with their individual area code numbers. The completed cards are transmitted to the statistical methods section where they are mechanically punched in preparation for the required tabulations. Because mark sense cards are punched mechanically, their use eliminates the process of manual punching which would be required if any other type of record were used. However, where the volume of cards is small and IBM equipment is not available, the system is well suited to a marginal punchcard.

Information Recorded

This card provides for the recording of the following kinds of descriptive and identifying data concerning services:

Health department program (columns 25-27). Service consultants frequently provide services to more than one program during a single conference or other activity. For that reason, three identical program columns have been provided allowing for the recording of as many as three different programs served

during any one activity. For example, an individual conference is held with one person during which maternity, child health, and chronic disease problems are discussed. In this instance, the one person receiving service would be recorded as one in the "number in attendance" columns. In the program columns, all three programs are indicated: maternity would be marked in one program column, child health in the second, and chronic diseases in the third. However, there is no significance to the sequence of the three program columns; the marking of these three programs in any other sequence would be equally acceptable.

This method of recording makes it possible to obtain two types of counts; a count of total persons served without regard to programs and a count of persons served in each program. Machine tabulating procedures make it possible to count this person once in each of the three program columns and once in the total column (table 1). In other words, the total column refers to total persons served, some of whom may have been served in more than one program. Because a recipient frequently receives service related to more than one program, the sum of the persons served in each of the programs is usually greater than the total number of persons served. From these two types of counts, it is possible to obtain valid percentage distributions of services by program (table 4).

The geographic area (columns 19-21). The geographic code refers to the location of the recipient of the service. It identifies the following: individual counties, a few special cities, regions of the State, the State at large, the United States other than Michigan, and foreign countries.

The agency (column 18). Agencies with which the recipient of the service is associated are identified according to the local health department, hospital, private organizations, and other State agencies.

Personnel category (columns 16, 17). To record the work of the recipients, certain categories of personnel are identified by the code on the back of the card. Additions have been made as new programs have been included in the system.

MICHIGAN DEPARTMENT OF HEALTH

¹The back of the card lists categories of personnel by numerical code.

Number in attendance (columns 22-24). Space is provided for recording as many as 999 in attendance or recipients of service per activity.

Activity (column 14). Activities have been classified in broad terms with the idea of making them applicable to all health department programs; they are conference, talk, institute (workshop), inspection, training, casefinding, and other. The number of each category of activity is obtained by a simple card count since one card is recorded for each activity. The number of people served by these respective activities is the sum of the numbers recorded in the columns for number in attendance.

Servicing unit (column 15). This column serves as a subdivision of the activity column and makes it possible to differentiate between individual and group activities.

Identification of service worker (column 13). The code used for the worker is a four-digit number representing the health department position which the worker is currently filling. Since this number remains constant until the position is abolished, the number does not change with a change in staff, and, therefore, gives continuity in reports. This number is so

constituted that the division, section, and unit of the department are identified by the first three digits, which are prepunched in specified columns of the cards leaving only the fourth digit for the worker to record to identify himself. This makes it possible to combine cards from all divisions of the department and still be able to identify the division, section, unit, and worker in tabulations of total health department services. Thus, a tabulation by program and the first three digits of the position number indicates the amount of service each division, section, and unit of the health department contributes to the total services in each program (table 2). Tabulations using the fourth digit of the position number provide summary tabulations of each individual worker's services (table 3).

Month of service (columns 11, 12). Only the month is marked by the worker; the last digit of the year is gang punched in a specified column for all program cards when received in the statistical methods section.

The items which have been discussed so far are believed to be applicable to all health department programs. For that reason, the terms used have been made as broad as possible.

However, some of the programs have certain types of services peculiar to their own programs which they also wish tabulated. We have reserved space for recording these items for the respective programs. One column is now used for special casefinding activities in the hearing program, and for special chronic disease information for nutrition and nursing. Other columns are used for hospital identification for the hospital consultation and the licensing section. This type of arrangement makes for uniformity, yet it is flexible enough to accommodate special program needs. ~

Purpose, Objective, and Philosophy

The purpose of this record system is to provide a feasible method of collecting these service statistics and a flexible means of tabulating them. The objective is to provide meaningful service statistics for program planning, administration, and evaluation which will be useful to the individual worker, the program director, and the administrator.

The system is primarily concerned with the recipients of health department services, the number of Michigan people and others who received service from the professional fieldworkers of the Michigan Department of Health. The number of recipients is a count of persons to whom services have been given and is not necessarily an unduplicated count of individuals. The item of activity as used here serves to indicate the method or means through which these services are accomplished. A count of these activities is not for the purpose of determining the amount of effort put into the job by each worker; instead, it is a means by which the amount of services accomplished can be related to the various work techniques, individual and group.

Only activities which provide services are reported in this system. For example, attending a professional meeting without participating is not recorded because no service was given. However, if there was participation in the meeting, then a service was given and the activity is recorded together with the number of people receiving the service. The first instance is for professional advancement while the second is a service given. Likewise, interdepartmental

planning conferences are not recorded; it is a foregone conclusion that effective services cannot be provided without previous planning and counseling. Also the time spent providing these services is of no concern in this system. When the time element is important, it can be considered more appropriately through special time studies.

Development

To establish the new system required several planning sessions over a period of time. In the beginning, several conferences were held between the chiefs of the nutrition section and the statistical methods section to determine types of data needed and the uses to be made of them. The statisticians met with the entire nutrition staff for an explanation of the philosophy and method of the new system. The staff assisted in defining terms and establishing rules for recording. Following this, the system was put into use. At the end of the first month, sample tabulations were run and summary tables prepared. These were jointly reviewed by the nutrition staff and the statisticians at the monthly nutrition staff meeting to which the director of the division of local health services and the director of the division of administration were invited.

Throughout the year, monthly tabulations were reviewed jointly with the nutrition staff at their monthly staff meetings. This continuing process provided a means of refining definitions and policies and developed a common understanding of the philosophy, problems, and methods of recording. At the end of the year, annual tabulations and summaries were prepared. Also, a few graphs were prepared showing the percentage distribution of nutrition services by program and by agency. This was the first time annual service statistics had been available on either a program or agency basis.

Again the directors of local health services and administration were invited for the review and expressed considerable interest in the value of these statistics to the department as a whole. The director of local health services said that the actual figure of total people served together with the subdivisions by program would be

seful in verifying the fact that the State health department had rendered specific services to certain individual health departments. The director of the division of administration felt that the figures by program would be useful in justifying categorical funds and helpful in making a more equitable distribution of them among the organizational units of the department.

At the end of the second year, annual summaries and charts were again reviewed. This time the charts were designed to compare the 2 years, keeping in mind, of course, the changes in size of staff. At the end of the third year, it was possible to prepare charts in the form of line graphs indicating trends and summary tables in the form of time series. At this point, it became possible to take a new look at the program from the standpoint of both the past and the future—in other words, to evaluate what had been done and set goals for the future. With 3 years' accumulation of data, the system took on new meaning and value for the program people.

During this period of development in the nutrition section, the director of the maternal and child health division suggested that this system be applied to some of her programs where a rather extensive code system of reporting was being used. Also, during this time, the system was reviewed by the Research and

Statistics Committee of the department composed of representatives of most of the health department programs. The representatives from local health services and administration were already familiar with its advantages and were helpful in conveying to the other members of the committee the advantages of the system to the department. The committee, including the director of the maternal and child health division, recommended that the system be extended to other organizational units. The director also suggested that the extension begin with three of her programs—hearing, vision, and hospital services. The statisticians then held meetings with the director of the maternal and child health division, her section chiefs, and staff members of these program units; these meetings were similar to those held with the nutrition section.

Not long after the system was underway in these programs, the chief of the nursing section requested that her program be considered next. Similar procedures of indoctrination were carried out with this section. Basically, the definitions and terms used for nutrition were acceptable to the other programs but needed to be related to the specific programs. It was obvious that the preliminary conferences and meetings with the nutrition staff were paying dividends. Relatively few changes have been necessary in the nutrition definitions and

procedures. The problems ironed out with that program reduced considerably both the problems and time required to establish the system in these other programs. However, successive

adaptations to new programs have helped to sharpen the definitions and to clarify policies for all programs. Trends are now available for all of the five programs and the annual sum-

maries are becoming more and more valuable to the program directors each year.

Cross Tabulations of Data

Cross tabulations of the items in this system provide a wealth of information about health department services that have been given and all attention to the need for services where they have not been provided.

The cross tabulation of program and agency in table 1 shows the distribution of nutrition services to the various health department programs as well as to the several agencies. Similarly, for each program, there is a distribution of services by agency and for each agency there is a distribution by program. For example, the chronic disease services to 4,250 people represent well over one-third of all nutrition services; of these, 1,629, or 38 percent, were with private agencies; 1,143, or 27 percent, with local health departments; and 6 percent with colleges. Agencywise, hospitals received maternity, child health, tuberculosis, and chronic disease services as well as generalized nutrition services from the nutrition section.

Table 2 is a sample of a composite picture of health department services by program, the sum of the services contributed by each organizational unit. The sample includes the five organizational units currently using this system.

Table 3 gives a more detailed picture. It is a summary of the individual worker's services. From this, he knows how many persons he has served in each program by geographic area, agency, category of personnel, and by which method or activity these persons were served. For example, the line marked with an asterisk in table 3 is interpreted as follows: nutrition worker No. 2 held an individual conference with a local health department nurse in area 5 during which she provided service in relation to maternity, child health, and chronic disease.

Table 4 illustrates a continuing annual summary of the number and percentage distribution of nutrition services by program. The marked drop in services in 1954 is noticeable and was due to a decrease in staff. Since that time, some of the local health departments have employed nutritionists on their staffs with the result that fewer of the nutrition services to the State as a whole have been given by State-employed nutritionists. The increase in chronic disease service is also noticeable; this is the result of the recent responsibility of the health department for the licensing of nursing homes and homes for the aged.

Table 5 relates the number of activities to the number of people served and indicates the trend over the years. The services provided by means of conferences have consistently

NOTE: Figures for 1954 not available.

ranged between 80 and 90 percent of all activities, serving between approximately 25 and 38 percent of the people. Although not shown in this table, it is possible to subdivide conferences into "individual" and "group" to further relate the activity to persons served and to indicate the amount of group approach.

Figure 2 shows the number of recipients of the various program services on semilogarithmic graph paper which indicates not only the relationship between the number of services in the several programs but also the rate of change in the number of services in each of the respective programs. The drop in tuberculosis services during 1955 and 1956 alerted the nutrition staff to the need for conferences with the staff of the tuberculosis division.

Uses

These service statistics are used for—
 Special program reports.
 Staff meeting discussions.
 Program reviews, evaluations, and planning.
 Developing and administering training programs.

In order to—
 Orient new employees.
 Write annual reports.

Point up areas for special studies and special program emphasis.

Justify increased budget and staff; distribution of categorical funds; and reorganization of program plan.

Indicate areas of progress and of need.

Evaluate local use of State consultants.

Determine services provided in areas of the State without health departments.

Provide information to legislative and budget authorities.

Monthly and annually, the program director receives a copy of the tabulation of total staff services and a copy of each individual worker's services. The individual worker also receives a copy of the total staff services but only a copy of his own individual services, not those of his co-workers. It is important that the individual worker receive a report of his services to provide him with the means of evaluating and planning his own work, as well as to receive something valuable and useful in return for his efforts of recording data. This makes him better able to see his services in relation to the total services of his organizational unit, a factor conducive to the team approach.

Reviewing monthly and annual summaries at

staff meetings is very valuable to the individual worker as well as to the program director because each worker has an opportunity to see the overall result of the combined efforts of the staff as well as his own contributions. This type of review also frequently serves as a self-correcting device. It is not uncommon for questionable figures to appear and after some discussion, it is discovered that there is lack of uniformity among the staff in recording their services. For example, it was learned that for services in nursing homes, some workers were coding them as "private" and some were coding them as "institutions." These examples of misplaced data due to miscoded reports are of tremendous assistance to the worker in helping him to more fully understand the categories of information which he is asked to code on the record. Knowing where he wants his efforts to appear in the

summary reports helps him to code his services more accurately.

These continuing annual summaries provide the program directors with data helpful not only for future planning but also for deciding emphasis in program operations. After 2 successive years of decreasing nutrition services to the tuberculosis program, the nutrition section assigned a graduate nutrition student the project of determining the reason for the decline in tuberculosis services and also to discover where these services were most needed in the program. This information also served as the basis for joint conferences with the tuberculosis and adult health division to review their total program with special concern for nutrition emphasis. This created an awareness of the services available from the nutrition section.

The nutrition section also makes extensive use of this information in State and local training programs. Their graduate students and trainees in local health departments also use this system to record their services and send them in to the State office, thus providing actual figures which are convincing evidence that trainees give a great deal of service while they are being trained. These factual data indicated that the nutritionist provides a departmentwide service to the local health department programs, thereby justifying the expenditure of money to establish a nutritionist position on the staff. So far, two local health departments have established nutritionist positions on their staffs. One of the local health officers requested from the State the service statistics of his nutritionist to include in his annual report.

The fact that the State health department also has the statistics from the local areas makes it possible to evaluate not only the nutrition services of the State staff but to have information concerning total nutrition services given within the State, by State and local health departments. In other words, the system provides a means of both selling and evaluating. More and more graduate schools are becoming concerned with training for supervisory nutrition positions. To date, three students have come to Michigan for supervisory field training. The interpretation and use of this system provided the basis for the most important part of

So far, two local health departments have established nutritionist positions on their staffs. One of the local health officers requested from the State the service statistics of his nutritionist to include in his annual report.

The fact that the State health department also has the statistics from the local areas makes it possible to evaluate not only the nutrition services of the State staff but to have information concerning total nutrition services given within the State, by State and local health departments. In other words, the system provides a means of both selling and evaluating. More and more graduate schools are becoming concerned with training for supervisory nutrition positions. To date, three students have come to Michigan for supervisory field training. The interpretation and use of this system provided the basis for the most important part of

Figure 2. Number of recipients of nutrition services by program, Michigan Department of Health, 1953-58

their training. It is a concrete constructive device to use in training and supervision and a tool which they can use in the future.

The first annual summary of the hearing program pointed up the volume of casefinding services and the proportionately small amount of consultant service. The maternal and child health director and hearing consultants had been aware of this situation and realized that consultants on the State level should provide more consultant service and do less casefinding. A bar diagram chart of these services pointed up the relationship very sharply and gave support to the hearing program's long-range plan for decentralization. Plans were made for further decentralization of casefinding activities. This resulted in many local health departments employing hearing conservation staff.

Comments

Comments have been received from two program directors using this system to the effect that because they are accustomed to working with and thinking in terms of individuals, it is hard for them to think in terms of large numbers. This is particularly true of some of the people trained in the clinical field. They recognize the need for service statistics but find it difficult to know how to record them or how to think in terms of counting them. Once these data are summarized, related to each other, and presented in such a way as to indicate trends

over the years, they can readily relate past incidents and problems of their programs to the fluctuations in these trends. With this visual impression of the past, they can more readily visualize their future goals. Also, they are much more aware of the relative position that each part of their work contributes to their total program and are able to adjust their activities and program content according to their goals; for example, the people in the hearing program further decentralized their casefinding activities and the nutrition people took steps to increase their services to the tuberculosis program.

Summary

As the scope of public health takes on new proportions, the number of public health disciplines increases and, consequently, a greater need arises for service statistics by program for health departments as a whole as well as by specific divisions within the department. These statistics are valuable not only for program planning and evaluation, including training programs, but as documentary evidence for budget requests, justification of categorical funds, and as an aid in making an equitable distribution of services and funds.

This account describes the development and use of a mark sense punchcard system for obtaining service statistics. With this system, collection of the data is simple and the tabulating possibilities are both multiple and flexible, providing useful information for the individual worker, program director, and administrator.

Safety Leaflet for the Aging

"Getting on Safely," a leaflet to help aging men and women to avoid accidents, was recently published by the National Safety Council.

Among men and women over 65 years of age, the incidence of fatal and crippling injuries is relatively high. Three-fourths of all accidental deaths from falls during 1957 occurred in this age group.

A sample copy of the leaflet may be obtained free of charge from the National Safety Council, 425 North Michigan Avenue, Chicago 11, Ill. The minimum purchase order accepted is for 50 copies (\$2.80).

Public health nurses discover an outbreak of staphylococcus in a New York State hospital nursery through a 10-month surveillance of newborn infants at home.

Staphylococcal Outbreaks in Infants Detected after Hospital Discharge

ANDREW C. FLECK, Jr., M.D., M.P.H., and MALCOLM BOUTON, M.D., M.P.H.

IN HOSPITALS in upstate New York, most newborn infants stay only 4 days. Since this stay is shorter than the average 6-day incubation period of hospital-acquired staphylococcal disease in newborns (1-6), a nursery outbreak may be detected only by examination of infants after discharge.

The feasibility of having public health nurses examine infants after discharge was explored during a 10-month survey in one city served principally by three hospitals. When the survey began in May 1958, there was no reason to believe that any of the hospitals had a staphylococcal disease problem in their nurseries.

The city's resident population was 97,999 on July 1, 1958, as estimated by the New York State Department of Health. Its 3 hospitals, which also serve the surrounding suburban and rural areas, have nursery units with a maximum capacity of 12 bassinets in each unit. The nurseries are not overcrowded, and they were inspected and approved during the preceding year as complying with the provisions of the

New York State Sanitary Code. This code establishes standards for physical features and nursing and medical management of nurseries. The three hospitals are identified here as "A," "B," and "C."

Methods

The public health nurses employed by both official and voluntary agencies were told the purpose of the study at a series of meetings.

No effort was made to select a random sample of infants or to add to the current caseload of the visiting nurses. Infants were already being visited as part of the maternal and child health program. The policy was to visit all infants of primiparae within 1 to 2 weeks after birth. The nurses were asked to take a history and record their observations of the presence or absence of pustules, vesicles, bullae, and other types of skin infections. Information recorded for each infant included the nurse's description of the skin infection and the date of the nurse's visit, in addition to the infant's name, date of birth, and hospital of birth.

An infant was classified as positive on the basis of a history or presence of skin pustules or more severe suppurative disease. Suppuration was felt to be a more specific index of staphylococcal disease than the vesicular bul-

Dr. Fleck is an epidemiologist with the New York State Department of Health, Albany, N.Y. In addition, he is acting head of the department of community health, Albany Medical College, Union University, in Albany, where both he and Dr. Bouton are assistant professors of epidemiology.

lous, erythematous, or papular rashes which are fairly common in the newborn. Suppuration was also more easily identified and described by the mother and the nurse.

A preliminary analysis was made to determine the relationship between the age of the infants at the time of the nurse's visit and the possible dates of onset of staphylococcal disease. Of 344 routine neonatal visits during a 3-month period, 316 visits were made between the 6th and 20th day following birth; 177 of these were made between the 9th and 12th day. It was felt that this timing was optimal, since our previous experience in New York State nursery outbreaks had shown that the onset of pyoderma occurred most commonly before 10 days of age (1). It was recognized that some cases which have longer incubation periods, such as breast abscess or pneumonia, might be missed.

Outbreak Findings

The attack rates for each hospital for the entire survey period were not significantly different (see table). The salient finding was the detection of a previously unidentified outbreak of staphylococcal disease in a sample of the newborn infants discharged from hospital B. The presence of an epidemic was suspected when 2 infants among 13 born in hospital B during the first week of November were discovered through the survey method to have signs of suppurative disease.

Neonatal suppurative disease in a sample of discharged hospital-born infants examined by public health nurses, May 1958-February 1959

Hospital of birth	Estimated total births	Number of infants visited	Number ill	Percent of sample ill
A-----	1,150	157	3	1.9
B-----	1,530	391	12	3.1
C-----	800	56	3	5.3
Other ¹ -----		6		
Total-----	3,480	610	18	2.9

¹ Resident births in hospitals in other cities.

NOTE: $n=2$, $x^2=1.66$

The suspicion was confirmed when subsequent visits to an enlarged sample of 46 infants born in this hospital discovered 6 infants with signs of suppurative disease. The suspect diagnoses were confirmed by a physician's examination. Phage typing identified the etiological agent isolated from the lesions as type 80/81 staphylococcus. Examination of all 233 infants born in hospital B during the epidemic period revealed a total of 20 cases of suppurative lesions including 1 death, and an attack rate of 8.6 percent. The types of clinical disease discovered are shown below:

Lesion	Number of infants
One or more skin pustules-----	11
Impetigo-----	4
Omphalitis-----	1
Conjunctivitis-----	1
Abscesses-----	2
Septicemia-----	1

The epidemic occurred in a 55-day interval November 1 to December 25, reaching its peak in 30 days and declining in 25 days. One mother developed a breast abscess.

The only death occurred in an infant born November 18 who developed pustules on the buttocks 4 days following birth, an upper respiratory syndrome after 1 month, and died with a type 80/81 staphylococcal septicemia when 8 weeks of age.

Excluding two premature infants with prolonged hospital stays starting before the epidemic period, the range of incubation period, as measured by the interval from the birth-date to the onset date of disease, was 2 to 10 days. The distribution of incubation periods is consistent with a common source outbreak (see chart). The modal incubation period was 3 days.

A bacteriological and phage-typing survey of the nares of personnel and infants ruled out both an infant nasal reservoir of type 80/81 staphylococci and carriers among hospital personnel working in the nursery. Nasal cultures were taken from 30 persons. Six persons were found to be carriers of coagulase positive strains, but none had the epidemic strain.

Two nurseries, equally affected, were on separate air supplies. A common airborne source such as dust or droplet nuclei was believed to

Interval in days from birth date to onset date of staphylococcal disease, hospital B epidemic cases¹

¹Data exclude two cases of premature infants born before epidemic period.

be unlikely. One nursery contained only isolette units and the other, conventional single infant bassinets of an approved design. The equipment used in the two nurseries was different and a common fomite source was also considered unlikely.

A source lesion among nursery personnel and a resulting spread of staphylococci by direct contact was suspected. However, physical examination of all personnel in contact with the nursery, conducted by hospital staff physicians, did not reveal any source lesions.

The reasons for the cessation of the detected epidemic were not discovered. Two factors may have been involved: the special attention given to aseptic principles as a result of the concern of the staff about the outbreak, or the spontaneous recovery or departure from the nursery staff of a worker with an unrecognized lesion discharging staphylococci.

Other Findings

In addition to the detected epidemic, examinations by visiting nurses provided an estimate of the nonepidemic levels of suppurative disease. Exclusive of the epidemic period in hospital B, 12, or 2.1 percent, of 564 infants visited

after discharge from the three hospitals were found to have evidence of suppurative disease. Of the 12 cases, 9 had only few or solitary skin pustules, 2 were classified as impetigo, and 1 had a purulent conjunctivitis. No bacteriological studies were made on these infants.

The nonepidemic level of infant suppurative disease, 2.1 percent, observed in this survey of primiparous births differs from that reported in the literature. Williams (7) reports endemic levels of 5 to 15 percent based on daily hospital observation of newborn infants for evidence of pustules, conjunctivitis, or other suppurative disease. Ravenholt (8) conducted a telephone survey of a sample of infants born in a hospital. Excluding 1 hospital with an epidemic, he found a pyoderma attack rate of 15.5 percent in a sample of 642 newborn infants discharged from 12 hospitals. Other investigators have found nonepidemic attack rates for infant pyoderma ranging from 5.5 percent to 22.0 percent, with most attack rates falling between 13 and 17 percent (9-14).

Aftermath

The survey technique using public health nurses is being followed in 12 counties in New York State, where 2,472 infants have been examined during the period July 1958 to April 1959. Eighty-three infants, or 3.3 percent, were observed to show evidence of suppurative disease.

This lower level of suppurative disease may be attributable to the enforcement of regulation 35 in chapter II of the New York State Sanitary Code, entitled "Precautions To Be Observed for Control of Diarrhea of the Newborn." Annual inspection of nurseries and adequate enforcement have eliminated to a great extent the hazards of overcrowding, neglect of handwashing, and other factors which encourage contact transmission of any communicable disease.

Conclusion and Summary

The rationale of the examination of infants after hospital discharge as a means of detecting nursery outbreaks of hospital-acquired staphylococcal disease is based on the assumption that

the incubation period is longer than the hospital stay. This study demonstrated that the technique will be applicable, even when the modal day of onset of disease coincides with the next-to-the-last day of hospital stay. In practice, minor pustular manifestations are not considered as a barrier to scheduled discharge. The removal of the cases from the hospital forestalls the detection of an epidemic unless someone initiates an intrahospital reporting system which can be used to develop data on attack rates of suppurative disease.

Surveillance of infants by public health nurses for evidence of suppurative disease after hospital discharge detected an outbreak of the disease in a hospital in one city. Exclusive of this outbreak, the nonepidemic level of staphylococcal disease in infants measured by the presence of suppuration was 3.3 percent in a group of 2,472 infants visited in 12 counties in New York State, and 2.1 percent in a group of 564 infants visited in 1 city.

Epidemiology Course for Nurses

A refresher course in communicable disease control, emphasizing epidemiological and statistical principles and techniques in terms of major communicable diseases, will be held from February 29 through March 18, 1960, at the Communicable Disease Center in Atlanta, Ga.

Communicable disease nursing consultants, public health nursing supervisors, educational directors, qualified public health staff nurses, industrial nurses, instructors in schools of nursing, and other nurses having supervisory, teaching, or consultant functions are eligible for admission.

Application forms and further information can be obtained from the Chief, Nursing Section, Epidemiology Branch, Communicable Disease Center, Public Health Service, 50 Seventh Street N.E., Atlanta 23, Ga., or from the directors of public health nursing of State health departments. Applications should reach the center no later than February 8, 1960.

Trends in the Care of the Mentally Ill

ROBERT T. HEWITT, M.D.

RESPONSIBILITY for care and treatment of the mentally ill is moving out from the mental hospital into the community, the outpatient clinic, the general hospital, the physician's office, and the home. There seems to be no immediate danger of the public mental hospital going out of business. However, there are indications of many efforts to find out what is the place of the mental hospital in the changing treatment picture.

As evidence has unfolded to indicate that the traditional mental hospital is not the most appropriate place to treat all mental illness and that the hospital itself may be a factor in the development of chronicity, statements have been made that "The mental hospital must go." More moderate opinion has been concerned with the need of modifying the old but also with developing other and hopefully more effective means of meeting the situation. The experiences of World War II, the advent of the tranquilizing drugs, studies of social scientists in mental hospitals, an aroused public conscience, and increased governmental interest—local, State, and Federal—have all been cited as responsible catalysts in the reaction.

Grants from the National Institute of Mental Health, Public Health Service, known as mental health project grants, are specifically designed to support projects for the development of new and improved methods in the areas we are discussing. These projects are pilot projects, experiments, demonstrations, and studies. The Office of Vocational Rehabilitation is also supporting projects in rehabilitation of mentally ill persons.

Mental illness is often precipitated by a crisis in the family, on the job, or elsewhere. Appropriate treatment given in an appropriate manner and at the appropriate time will often re-

store equilibrium, though not necessarily cure the patient of basic personality problems which make him prone to such crises. However, it may be possible for him to continue at home and at work without interruption or with minimal disruption. Commitment and hospitalization may be unnecessary and may make the total problem worse by disrupting the social and family situation. Like idleness enforced on muscles by immobilization of a limb, hospitalization results in some atrophy or regression with consequent prolonged recovery and more chance of developing chronicity. Of course, the nature of the illness may make hospitalization, even for long periods, the treatment of choice, but it has been shown that frequently it is not necessary. It has also been shown that hospital programs can be planned so that even the long-term patient is helped to reach his maximum level of functioning.

A corollary is that if social and family ties are not to be weakened, the patient should be treated as near home as possible, even if hospitalized. Also, if the patient is to avoid chronicity and relapse, rehabilitation and aftercare are necessary.

Alternatives to Hospitalization

Many of the new methods being tried out are called alternatives to hospitalization. While they are usually looked upon as substitutes for care in a mental hospital, they are steps toward

Dr. Hewitt is psychiatrist, Community Services Branch, National Institute of Mental Health, Public Health Service. This paper was delivered during the meeting of the State and Territorial mental health authorities in Washington, D.C., March 11-13, 1959, and appears in the proceedings of the meeting.

developing care and treatment methods which are appropriate to the illness and situation of the patient. They also represent an effort to achieve continuity of care throughout the different stages of a patient's illness. They are, for the most part, experimental and the subject of study at the present time. Very possibly in the future they may become essential elements in effective and comprehensive treatment programs. Many hospital administrators and others are convinced that construction of facilities for the care and treatment of the mentally ill must and will be modified in the light of the knowledge developing from current experimentation with these methods.

Some interesting projects are being developed to explore the ways in which early treatment can be provided in the acute phase of an emotional disturbance. Exploratory work is being done on the feasibility of establishing treatment teams available at any time to go out into the community to see patients immediately when a crisis arises which involves an emotional disorder. This is not only for the purpose of treating a patient early in his illness but is also based on the idea that the person did not become ill in a vacuum and it is necessary to see him in his own home or job situation to assess the environmental factors involved. Recommendations may be made or action taken which may involve referral to a nonpsychiatric agency, referral for treatment to a physician, an outpatient service or a hospital, or further diagnostic study by the emergency team.

A variation of this approach being explored is seeing each patient immediately as he comes to the outpatient department or the clinic, along with his family whenever possible. Here also an attempt is made to understand the problem in its psychological and social ramifications and to take action as quickly as possible. This is contrary to a familiar pattern of placing people on a waiting list for later consideration. It is hypothesized that many problems can be solved quickly and more efficaciously if attacked when acute and that a waiting list is not necessary. In many situations long-term psychotherapy is not desirable or required. Family counseling, environmental manipulation, or physical therapy may be the treatment of choice. There is evidence that conventional psychotherapy is not

suitable or effective in some socioeconomic groups.

Basically, day hospitals are outpatient departments, modified to fit the mentally ill patient. Patients are in the hospital for a varying number of hours during the day and then return home. The conventional outpatient treatment of 1 hour a day, successful with many mental patients, is not enough for the psychotic patient or for many neurotic patients. Diagnosis, treatment, and rehabilitation are functions of the day hospital. Various kinds of therapeutic activities may be added. These hospitals are usually open 5 days a week. Some patients may have daily appointments and some may come only when they feel the need. Day hospitals for children may be organized as schools with treatment of emotional disorders added. Others are organized as child guidance clinics with the school added.

Night hospitals are operated for patients who work during the day. They spend the evening and night at the hospital.

Many types of programs make use of the "halfway house." It is intended to be a transitional domicile for patients who do not require further hospitalization but are not yet ready to resume independent living. They live with other patients under some supervision in this transitional dwelling, moving gradually back into the community by reestablishing relationships through employment, social and family activities, and recreation.

This is a broad description of halfway houses. In practice they vary a great deal in organization, program, and auspices. For example, one halfway house is established specifically for the purpose of finding work for patients. Another provides not only supervision and social activities but also psychiatric treatment. Halfway houses in the community may be organized under official or voluntary auspices. Some are developed under the supervision of the mental hospital and may even be located in a ward of a mental hospital. In such cases the hospital regulations are liberalized with regard to this ward. Patients are placed more on their own responsibility with regard to movement in and out of the hospital. Definite and their activities within the hospital. Definite rehabilitation programs are organized for

them and they are encouraged to step out into the community.

Social clubs for ex-patients may be organized and supervised by professional people or they may be organized by ex-patients themselves. They attempt to provide some social life for ex-patients and in many instances offer counsel and advice as to sources of help: social, medical, and vocational. Some halfway houses are not residential facilities but in actuality are social clubs.

Followup and aftercare services for mentally ill patients discharged from hospitals are being extended. We need studies to help in planning the type of these services to develop. For example, how many and what kinds of patients want or need these services? What services may best be offered by the hospital or by the clinic? What should be provided by the official and voluntary health and welfare agencies in the community? It is generally agreed that a coordinated effort is a prime necessity. The public health nurse, the social worker, the vocational rehabilitation worker, the practitioner of medicine, and many others have a role to play just as they do in other human problems.

General Hospitals and Community Centers

Twenty years ago there were 48 general hospitals in the United States treating psychiatric patients. Now there are 500 to 600 with psychiatric units. Many others accept mentally ill persons for short-term treatment. This has been both a cause and a result of more psychiatrists moving into practice in communities. Factors in this trend have been the improvement in treatment techniques, the increased experience and confidence of psychiatrists that patients can be treated in general hospitals, and the increased understanding and leadership of hospital administrators. The length of hospitalization is usually short and no commitment is involved, so that there is less social disruption for patients and their families. Patients are often more amenable to the idea of going to a general hospital than to a mental hospital, and their attitude is frequently more favorable for treatment. Several States are experimenting with subsidizing the care and treatment of patients in the psy-

chiatric wards of general hospitals. These wards are for patients who would ordinarily be admitted to State mental hospitals. In other places attempts are being made to admit all mentally ill persons from a specific area to a psychiatric service to determine the feasibility of such care for all mentally ill.

Many psychiatric services are so large that they really operate as mental hospitals under the administrative umbrella of a general hospital. In other general hospitals, psychiatric patients are hospitalized with general medical patients and there are no separate wards. Without discussing in detail the advantages and disadvantages of treating patients in general hospitals, we already have abundant evidence that we should continue to move ahead in developing psychiatric services in these hospitals. We need to study the possibility of integrating care and treatment of the physically and mentally ill just as we need to appreciate that there are unique aspects to each.

Community mental health centers are conceived of as places where all mental health services, including prevention, promotion of mental health, consultative services, treatment, and aftercare services can be centralized. Treatment services may include all of those already mentioned. Experimentation with these centers has occurred mostly in urban areas. It is hoped that they will provide for the coordination of mental health services so difficult to achieve.

Mental Hospitals

Today there is generally a more hopeful atmosphere in mental hospitals. Although admissions are increasing, the total number of patients in our State mental hospitals has been decreasing slowly in the last few years. We do not know the meaning of these decreases as both discharges and deaths have increased. There is increased emphasis on treatment and rehabilitation which was additionally stimulated by the advent of the tranquilizing drugs. Studies of social scientists have pointed out that the hospital organization and procedures may promote chronicity. This has resulted in renewed efforts to discharge patients as soon as possible and to design rehabilitation programs for the patients who remain longer.

A recognized first step in producing a therapeutic community is to be sure that you aren't doing anything antitherapeutic. Most authorities, here and abroad, feel that the large mental hospital can be just that. We can't tear down these hospitals tomorrow, but we don't have to make the same mistakes in building new hospitals. Also, we can make important modifications in existing hospitals. Modern treatment ideas call for dividing hospitals into small treatment units so that the personnel and the patients can develop a close relationship and understanding. These units are being established in many older hospitals. This trend must be taken into consideration in planning new construction.

The increased emphasis on the therapeutic use of personnel and other treatment innovations, including the tranquilizing drugs, have made a great difference in the care of the so-called disturbed patients. Episodes of disturbed behavior occur but are treated more effectively. The old "disturbed" ward is almost gone. In hospitals of the future, security will be a minor issue as compared to what it has been in the past.

This brings us to a discussion of the open hospital. The idea of a completely open hospital began abroad and has many supporters in this country. Even though the open hospital movement has proceeded more slowly in this country than in the United Kingdom, the philosophy that patients are able to respond positively to more freedom has resulted in the unlocking of more wards throughout the country. Protagonists of the open hospital idea say that it reduces administrative problems and improves the attitudes of patients and personnel. They maintain that it is unnatural to lock patients up; that locked doors are a cause of a good deal of disturbance and chronicity in mental patients. It is evident that allowing patients more freedom makes it imperative to provide activities for them. It stimulates a reorientation of attitudes on the part of personnel and also has implications for hospital construction.

Planning of facilities must be preceded by good program planning if we are to avoid having programs determined by the kind of facilities available. The isolation of mental hospitals from physical care facilities, training

sources, and community health and welfare agencies, both physically and psychologically, has impeded the development of mental health programs. This calls for mutual study and planning.

The Aged

All States are grappling with the problem of the aged mentally ill. It is alleged that there are many aged patients in mental hospitals who really should be in their own homes, in nursing homes, or homes for the aged. This is one of our unsolved problems and we need more facts to deal with it. Just how many aged patients in mental hospitals could be cared for adequately in homes for the aged?

People who have been working with the aged believe that here, more than in any other age group, coordinated planning by those responsible for physical and mental health and welfare is necessary. The idea that aged patients once admitted to a mental hospital must die there has been discredited. Many older patients have transient psychoses, such as depression, which yield to treatment, both physical and psychological. Many of them require brief periods of hospitalization and then can go back to their own homes, or to nursing homes. Much more study and collaboration are needed in planning programs for the aged.

In Conclusion

What are some of the factors which we need to think about in planning for the future? The care of the mentally ill has been traditionally State supported and provided on a mass basis in large mental hospitals. But will this be the pattern for the future? I have indicated that there are alternatives to sending all mentally ill patients to mental hospitals and that short-time treatment in general hospitals is feasible for many patients. Vocational rehabilitation has made forward strides in the rehabilitation of the mentally ill in the last few years. In many places health insurance programs have extended coverage to some area of mental illness and studies are being initiated at the present time to investigate the cost of further coverage. Some union medical care plans are underwrit-

ing both treatment in general hospitals and outpatient treatment. Resources from social security benefits are available to an increasing number of persons. Patients and their families will be more able to carry the cost of short-term care if they are helped by insurance and if

treatment facilities are conveniently available to them. All of these factors must be taken into consideration in thinking about our total problem. They make clear the need for coordination in planning mental health facilities for the mentally ill.

Legal note . . . Sanitation

Sanitary district liable for property damage when clogged manhole caused sewage to back up and overflow into home. Duty of proper inspection of sewer lines. *Mulloy v. Sharp Park Sanitary District* (164 Cal. App. 2d 391, 330 P. 2d 441, October 1958).

Plaintiff brought an action for damages against the defendant sanitary district, alleging that the district created a private nuisance and was guilty of negligence in allowing a manhole of the sewer system operated by it to become clogged, causing the plaintiff's home to become flooded with sewage and debris. On appeal by the sanitary district, a jury verdict in favor of the plaintiff was upheld by the California District Court of Appeal.

The facts, as stated by the court, were that the district operated a sewer system consisting of a sewage collection system and a treatment plant. The system had about 500 manholes, and 1 manhole was located directly in front of the plaintiff's home, which was connected to the sewerlines.

On the day in question, when plaintiff flushed a toilet, water backed up in the toilet and bathtub, flooding the bathroom and other rooms in the house with about 4 inches of sewer water and debris, causing extensive damage.

When the defendant's employees were called, they found the manhole plugged and full of water. They dislodged a broom or mop from the sewer pipe connected to the manhole and there was evidence that there was other debris in the manhole.

The defendant's evidence indicated that all the manholes were routinely inspected about every 30 days. The manhole in question had been inspected the day before the occurrence complained of and no obstruction of the sewer was seen at that time. The inspectors, however, had not descended into the manhole but had merely lifted the cover and looked down, a process which took about 1 minute.

The defendant's superintendent also testified that it was good practice to conduct occasional flushings and cleansings of sewerlines, but the defendant did so only when the lines were obstructed. The line serving the plaintiff's home had not been flushed prior to the flooding.

The district contended that, as a public agency engaged in a governmental activity, it could not be held liable in the absence of a special statute. The court rejected this contention, holding that in California a governmental unit is liable for creating and maintaining a condition declared to be a nuisance by the legislature. Under the statutory definition of nuisance contained in section 3479 of the California Civil Code, as "Anything which is injurious to health, or is indecent or offensive to the senses, or an obstruction to the free use of property, so as to interfere with the comfortable enjoyment of life or property . . .," the court held that the facts in the case unquestionably constituted a nuisance.

Disposing of the district's argument that it could not be held liable for negligence, the court held that under the decided California cases a governmental agency was liable for negligent damage to real property. The limited inspection of the manhole, the court declared, supported an inference of improper inspection of the sewer system and upheld the finding of the jury that the district was guilty of negligence.

—SIDNEY EDELMAN, assistant chief, Public Health Division, Office of General Counsel, Department of Health, Education, and Welfare.

Occupational Health Notes

Sporotrichosis Among Miners

Mature spores of the fungus *Sporotrichum schenckii* in mine timbers afflicted more than 3,000 miners with skin lesions and internal damage before the source was detected and controlled, reports Dr. Rebecca Brown, Transvaal Chamber of Mines, Timber Research Laboratory, Johannesburg. She was in Montreal at the Ninth International Botanical Congress.

Castor Bean Pomace

Castor bean pomace, imported from South America for use in fertilizer, has caused outbreaks of illness in workers handling the material at eastern seaports. The pomace, which is the residue after oil is extracted from the castor bean, has long been recognized as capable of producing illness since it contains a powerful toxin, ricin, and a potent allergen.

An outbreak in Baltimore in February 1959 affected 18 of 45 railroad workers. Symptoms were upper respiratory distress, asthma, nausea, vomiting, chills, and fever. The Public Health Service found that similar incidents had occurred in Norfolk, Va., Wilmington, Del., and Tampa, Fla.

Recommendations to importers included steam treating, improved packaging and handling, and the use, where necessary, of protective clothing, eye protectors, and respirators.

Insecticide Hazards

Two young market garden workers in Massachusetts died as the result of insecticide poisoning. Over several days they had spent about 12 hours applying various kinds of insecticides including parathion. On the day they died, they worked the entire day dusting turnips with a powder containing 1.5 percent parathion. They used knapsack dusters. They became ill about 5 p.m., and 2 hours later were taken to the local hospital where atropine therapy was administered. Autopsies were not per-

formed, but the symptoms of the men were typical of organic phosphate poisoning.

The workers reportedly had been informed of the hazardous nature of the insecticide but were not required to wear respirators and protective clothing, although the equipment was available. The bags of insecticide carried warnings of toxicity but were not labeled "poison" and had no statement as to antidote or treatment.

Explosion in a Plastics Plant

Lack of proper identification on containers was the basic cause of an accident which took one life and extensively damaged a plastics plant compounding polyester resins.

Assigned to clean up the crib where materials were mixed, an inexperienced employee of the Michigan plant tried to consolidate two half-filled gallon jugs which he believed contained the same material. One jug contained DDM (methyl ethyl ketone peroxide in dimethyl phthalate); the other, cobalt naphthenate. An explosion and fire resulted.

The worker received burns over 95 percent of his body and died about a week later. Plant damage from fire was at least \$100,000.

State Radiation Regulations

The Kentucky State Board of Health has adopted comprehensive radiological health regulations, and the Tennessee State Industrial Hygiene Service last summer began registration of radiation sources, in accordance with the Radiological Health Service Act.

Compensation for Radiation Exposures

Ionizing radiation exposure may result in physical injury, wage loss, and possible limitation of the employee's capacity to continue to work. All these effects, weighed for workmen's compensation, may not be evident for years after the guilty exposure. Donald Ream, consultant to the U.S. Bureau of Labor Standards, stressed particularly the time factor at the First Annual Governor's Conference on Workmen's Compensation in New Jersey, saying that a rating should permit continuing evaluation. He told of 35 workers reported by the U.S. Atomic Energy Commission as having received the "maximum" radiation dose but who might not evince outward symptoms for years.

Despite unchanged attitudes, the majority of the recalcitrant tuberculous patients discharged from the California Medical Facility during a 6-year period generally remained under medical supervision, and the disease of more than half of them became inactive or probably inactive.

Followup of Tuberculous Recalcitrants

EDWARD KUPKA, M.D., and DOROTHY L. GIBSON, P.H.N.

PRIOR to 1949 local health departments in California, except in Los Angeles County (1), frequently had difficulty in enforcing the isolation of infectious tuberculous patients who refused to cooperate. It was usually difficult to make sure that home isolation was being maintained; few county hospitals had facilities for escapeproof custody; and local jails generally were unsuitable for the detention of a person with infectious tuberculosis. Although the uncooperative tuberculous were a very small proportion of the total number of known patients, each was an unquestioned hazard to community and family and absorbed a disproportionate amount of the time and effort of health department workers.

Enactment of specific laws dealing with tuberculosis by the California Legislature in 1949 encouraged new approaches to the difficulties. These laws designated the disease as a public health menace; defined in detail the responsibilities of the health officer and other law enforcement officials in tuberculosis control; and specified the powers and duties of the health officer in enforcing isolation of infectious cases (2).

The legislation empowered the California State Department of Public Health to establish a hospital unit for recalcitrant patients to which violators of isolation could be sent by

the courts. The law also protected tuberculosis patients against indiscriminate incarceration by stipulating that the health officer must be ready to present evidence at court to verify the hazard of the individual's disease to the community.

With the cooperation of the California State Department of Corrections, a 20-bed unit with both hospital and prison characteristics was established in 1950 for male tuberculous recalcitrants. First located in temporary quarters at Terminal Island near Los Angeles, the unit was moved in 1954 to the newly constructed California Medical Facility near Vacaville in northern California. Meanwhile, as use of the facility increased, the number of beds available was increased to 50, with an average occupancy of 40.

The California Medical Facility was established to care for male felons from the State prisons who require special treatment for physical or psychological illnesses, including tuberculosis (3). The tuberculous felons and recalcitrant tuberculous patients sentenced by the courts for the specific misdemeanor of violation of isolation are cared for in the same section of the hospital. Medical and nursing services are provided by the institution staff. Individual and group psychotherapy, as well as occupational and recreational therapy, are available on a voluntary basis when permitted by the clinical status of the patient.

Although the local health officers now have a legal weapon of great utility, the law has been used conservatively. Annually, only about 1 in

Dr. Kupka is chief, and Mrs. Gibson, the nursing consultant of the bureau of tuberculosis control, California State Department of Public Health, Berkeley.

500 patients under health department supervision has been sentenced to the facility. Education and persuasion are tried repeatedly before the health officer turns to legal procedures. Court action is almost always against an offender who has repeatedly disregarded the most elementary protective practices and violated isolation orders. Local judges have seldom failed to act upon the health department's complaint in such a situation. If the trial does not result in incarceration, the court at least puts the offender on probation, on condition that he return to the sanatorium and remain there until dismissed medically.

The California State Department of Public Health screens admissions to the medical facility, assists in establishing general treatment policies of the tuberculosis section, and sometimes participates in the legal processes. At first the screening was necessary to keep the number admitted within the unit's capacity, but it also has enabled the department to request reconsideration of an occasional commitment when the evidence of contagiousness was out of date or not convincing. In earlier years it gave the department an opportunity to discuss the legal action with the local judge, sometimes voiding an improper commitment.

Between December 1950 and December 31, 1956, 211 recalcitrant tuberculous patients were admitted to the California Medical Facility. What happened to these men? How many have been lost to observation? How many are still alive? Over several years, has the disease of most of them improved? Are they currently under supervision or care? Have their attitudes changed?

Since the State bureau of tuberculosis control keeps only an admission and discharge file, limited to basic identifying, medical, and legal data, followup information was obtained from questionnaires sent to the 37 local health jurisdictions from which one or more persons had been sent to the facility for recalcitrants. Name, age at admission, facility file number, dates of admission and discharge, and length of sentence of each of the patients were abstracted from the basic file and typed on a questionnaire before it was sent to the appropriate health department. The local health departments were asked to add from their records of the patients

the last-known status of disease, interval since last examination, type of present medical supervision, admissions to other tuberculosis hospitals since discharge from the facility, marital status at time of first admission, and attitude since discharge.

Twenty-eight of the 211 patients were in the California Medical Facility on December 31, 1956, and were not included in the study. A total of 183 questionnaires were sent, and all but 2 were completed and returned. This excellent response may be interpreted as reflecting the strong interest of the local health departments in the legal detention program.

The responses indicated that 22 of the 181 were known to be dead; 6 died while in the facility; 16, after discharge. The remaining 159 patients constitute the group analyzed in tables 1-4.

About three-quarters (131) of the patients were in the age group 25-50 years. In this sample few young adults and oldsters were recalcitrants. The age of patients at first admission to the facility was as follows:

<i>Age group (years)</i>	<i>Number</i>
Under 20.....	4
20-24.....	6
25-29.....	26
30-34.....	27
35-39.....	21
40-44.....	25
45-49.....	32
50-54.....	15
55-59.....	10
60-64.....	5
65 and over.....	8
Not stated.....	2
Total.....	181

Negroes and Mexican-Americans each comprised 13 percent of the group; there were no Chinese or Japanese.

<i>Ethnic group</i>	<i>Number</i>	<i>Percent</i>
White.....	125	70
Negro.....	25	13
Mexican-American.....	24	13
Indian.....	3	4
Filipino.....	1	
Not stated.....	3	
Total.....	181	100

The marital status of the group at time of admission was in marked contrast to that of the male adult population in general. At the time of first admission, only 42, or 23.2 percent, were married and 89, or 49.2 percent, were single, separated, or divorced. The status of 50, or 27.6 percent, was not known or not stated.

As expected, the most populous jurisdictions in the State sent the most patients to the facility. However, 37 of the 47 full-time health jurisdictions in California have sent a patient to the facility on at least one occasion. Such wide acceptance reflects the need for this kind of institutionalization and also the willingness of the local health officers to utilize this legal resource after other means of achieving control of the infectious person have proved futile. Since Los Angeles County operates an excellent comparable sheriff's facility at Mira Loma, the health departments in that county have usually sent only recidivists or individuals with significant prison records to the State facility.

The following observations concern only the 159 patients who were known or presumed to be living at the time the data were gathered.

Table 1 indicates the strong possibility of satisfactory outcome of the disease even in tuberculous patients of the type covered by this report; the disease status of 91, or 57 percent, was known to be inactive or probably inactive.

After discharge from the facility, some of the

individuals were lost to observation. Since the status of 13 of the active and probably active group had not been checked for a year or more and 11 had dropped out of sight so that no data were available, it is clear, but not surprising, that the patients in the group continue to present caseload problems (table 1).

Table 2. Attitude after discharge of recalcitrant tuberculous patients, California, 1950-56

Patient's attitude	Last-known status of disease					
	Total	Active	Probably active	Inactive	Probably inactive	No data
Total.....	159	53	4	85	6	11

Unimproved:						
Same.....	85	37	2	41	3	2
Worse.....	2	1	0	1	0	0
Unknown.....	34	3	1	20	2	8

Attitudes of the patients toward their disease, judged in the broadest terms and, of course, highly subjectively, are shown in table 2. When these data are compared with those in table 1, it is evident that improvement in the status of the patient's disease had occurred in many cases without a corresponding change in the patient's attitude. Thus, although 72 percent of the patients had been examined within 12 months (table 3), only 24 percent were reported as having an improved attitude toward the care of their disease.

The majority of the surviving group were not living with family, and many of them continued to lead a nomadic existence. From information volunteered on the questionnaires, it was evident that many of them were alcoholics. In members of such a group a change in attitude in the direction of cooperation with a public agency is perhaps not to be expected. Nevertheless, for these patients legal isolation accomplished at least two important and previously unattainable objectives. First, it reduced the length of time the patients could spread tuberculosis to others, and second, the medical and surgical therapy given the patients led to eventual arrestment of disease in a considerable number.

Table 1. Last-known status of disease of recalcitrant tuberculous patients,¹ California, 1950-56

Probably inactive-----	6	4	0	1	1
Activity undetermined or not stated-----	11	4	0	4	3

Patients discharged from the recalcitrant unit are routinely transported to their own health jurisdictions by the sheriff's department of that county. The discharge occurs on the last day of the sentence, that is, 6 or 12 months after admission, depending on whether the patient is serving a first or subsequent sentence. If further treatment is needed, and it often is, the patients are immediately admitted to a tuberculosis hospital, usually the one operated by the home county.

Table 4 shows 245 later admissions to any tuberculosis institution for the group. Ex-

Table 4. Admissions¹ to tuberculosis hospitals after discharge from California Medical Facility among 159 recalcitrant tuberculous patients, California, 1950-56

¹ Includes readmissions.

² Against medical advice

cluding 23 readmissions to the recalcitrant facility, which is escapeproof, the remaining 222 admissions eventuated in 92, or 41 percent, subsequent unauthorized departures, a further verification of the failure to change attitudes. Of the 23 readmissions to the California Medical Facility, 4 were accounted for by 2 patients, who each had been sentenced to 3 separate terms in the prison ward.

This is to be considered as a progress report and from it no solid evaluation of the impact of this type of program upon the control of tuberculosis can be made. It would be useful to compare a group of recalcitrants who were not incarcerated and to note any differences in the behavior of their disease. Even more valuable would be a comparison between the number of new secondary cases attributable to contact with members of a nonincarcerated group and the secondary cases attributable to a group such as the one described in this paper. However, the excessive mobility, evasiveness, and social instability of the patients make such long-term studies extremely difficult.

Summary

Sentencing recalcitrant tuberculous patients to a special State facility by court action has proved practicable and useful in California. Use of this legal procedure not only has decreased the hazard of transmission of disease but also has created an opportunity for the commencement or continuation of much needed treatment for the patients.

Although the attitude of the majority of patients did not improve as a result of their incarceration, most of them remained under some type of medical supervision following discharge, and three-quarters had been examined during the 12 months preceding receipt of the questionnaire sent to the local health departments. However, many evaded regular medical supervision, especially after 1 year; one out of eight patients had to be readmitted to the State facility; and a third of those subsequently admitted to local tuberculosis hospitals again resorted to unapproved self-discharge. Nevertheless, the data indicate that by the time of the study more than half of the patients had

reached the classification of inactive or probably inactive.

The majority of health jurisdictions in the State have sent at least 1 patient to the facility, which would indicate that it is meeting a real need, but the small total (211 in 6 years) indicates that it is not being used indiscriminately or excessively.

films

Recognition of Leprosy

16-mm. motion picture, color, sound, 13 minutes, 1959, not cleared for television. (Order No. M-374.)

Audience: Practicing physicians and medical students.

The clinical manifestations of leprosy are depicted as they appear in patients of the Public Health Service Hospital at Carville, La. Techniques of taking and staining skin scrapings to demonstrate the etiological agent, *Mycobacterium leprae*, and of taking skin biopsies to demonstrate pathology of peripheral nerves are shown. Diagnostic procedures are included.

The film is not for sale. It is available on short-term loan (United States only) from the Communicable Disease Center, Public Health Service, Post Office Box 185, Chamblee, Ga.

Staphylococcal Disease: Manifestations, Prevention, and Control

35-mm. filmstrip, color, silent, 36 frames, cleared for television, 1959 (Order No. F-343).

Audience: Doctors, nurses, hospital personnel.

Various clinical manifestations of hospital-acquired staphylococcal disease, how it is spread, and some of the techniques and methods useful in the control of infections are depicted in stylized drawings.

Included with each filmstrip is a "kit" which contains an instructor's guide, bibliographies, hospital checklist, suggestions and a sample form for telephone surveys, and pertinent reprints. The requestor may keep the kit, whether the filmstrip is borrowed or purchased.

For short-term loan, in the United States only, the filmstrip is available from the Communicable Disease Center, Public Health Service, Post Office Box 185, Chamblee, Ga.

It can be purchased at approximately \$5.10 f.o.b. New York (10

Aseptic Technique—Handwashing

16-mm. motion picture, color, sound, 3½ minutes, cleared for television, 1959 (Order No. M-375).

Audience: Nurses, student nurses, medical students, physicians.

This film shows a method of handwashing, using cake or liquid soap, that may be used in the hospital and modified for use in the public health field.

It is available, in the United States only, on short-term loan from the Communicable Disease Center, Public Health Service, Post Office Box 185, Chamblee, Ga.

Prints can be purchased, at approximately \$28 f.o.b. New York (10 percent discount for nonprofit organizations), from United World Films, Inc., 1445 Park Ave., New York 29, N.Y.

Epidemic Crisis in East Pakistan

April-July, 1958

THOMAS A. COCKBURN, M.D.

A crowd of 2,000 women and children saw a health show in a village near Comilla, East Pakistan. Health shows were used to further a mass vaccination campaign during the 1958 smallpox epidemic. About 30 million Pakistanis were inoculated.

EPIDEMICS of smallpox and cholera began in October 1957 in the Eastern Province of Pakistan, and by April 1958 about 1,500 people were dying each week. The Province's public health services, desperately short of money, staff, and equipment, were hard pressed. In the first 6 months of 1958, the smallpox cases reported were 44,736 and deaths, 20,444. The cholera cases reported were 10,438 and deaths, 6,684.

On April 9 the Chief Minister delegated responsibility for all matters pertaining to the epidemic to a citizens committee of 60 persons, while everywhere volunteers began a vast, spontaneous, uncoordinated vaccination effort. Twenty-one nations, the World Health Organization, and several voluntary agencies sent East Pakistan a total of 8,243,000 cc. of dry vaccine and 18,284,025 cc. of lymph vaccine for smallpox, and 2,475,600 cc. of vaccine for cholera. Five international teams came to give epidemiological assistance.

Ten days after an appeal for help, the first shipment of smallpox vaccine arrived from the United States. By the middle of May, 40 percent of the 46 million population of East Pakistan had been vaccinated, which meant a vaccination rate of more than 1 million per week, and the supply of vaccine was satisfactory. In June, 2 million people a week were inoculated; the number of new cases dropped to 300 a week from a peak of 3,000 a week in May; and a practical means of eliminating the disease in East Pakistan was being developed. Late in June the monsoon began. By July cholera had disappeared, smallpox became less severe, vaccinating had almost ceased (figs. 1 and 2), and by the end of the month the international teams had left the Province.

About 30 million people were vaccinated in the first 6 months of 1958, a substantial achievement in any country, but under the conditions prevailing in East Pakistan, it was remarkable.

The Setting

The 46 million people of East Pakistan live on the delta of the Ganges and Brahmaputra Rivers. Most of them are Moslems, and many of the women are still kept in purdah.

The Province is almost entirely agricultural. Dacca, the capital, with 600,000 people, and Chittagong, with 300,000, are the only sizable cities. The land consists of silt deposited by the rivers, and when the monsoon breaks in June much of the land, only a few feet above river level in the dry season, disappears under water. The Province is crisscrossed by waterways, varying from a few yards to more than a mile in width, and outside the towns and villages, boats are the easiest and most common means of travel.

Since there are no stones in the alluvial soil, buildings and roads are made of bricks. Every village, hamlet, or row of houses has one or more water tanks, formed where clay has been removed to make bricks or to raise the land to a level above the flood waters. These water tanks are the center of village life, where people come to bathe, wash clothes, urinate, defecate, and collect water for cooking and drinking.

Public Health Service

East Pakistan had departments of medical care, public health engineering, and public health which were responsible to the Minister of Health through the Secretary.

The Department of Public Health which faced the smallpox and cholera epidemics was small. It consisted of a director, 4 assistant directors, 5 district health officers, 12 doctors working on a BCG program financed by UNICEF, 3 doctors helping a village aid project, a small malaria unit, and vaccine laboratories. The department's budget in 1958 was 5 million rupees (\$1 million).

The administration of public health was decentralized so that local authorities based in the Province's 17 districts and in the municipalities employed their own staffs with financial assistance from the department. Only 5 dis-

Dr. Cockburn of the International Cooperation Administration serves as provincial public health adviser of the Government of East Pakistan. He is former deputy chairman of the East Pakistan Epidemic Control Committee and director of the Institute of Public Health in Dacca.

Figure 1. Cholera cases and deaths, East Pakistan, 1958

trict health officers were directly responsible to the director of public health; the other 12 were controlled indirectly through financial assistance.

Each district of 800,000 to 5 million people is divided into 1 to 5 subdivisions, which are in turn divided into police areas, or thanas, governed by union boards. The boards pay chowkidars, the village police, who also report births, deaths, and notifiable diseases when they visit the police stations twice a week.

The thanas also have trained sanitary inspectors who train their own small staffs of health assistants and vaccinators. They are responsible to the district health officer, and, in theory, carry out all health duties. East Pakistan has about 400 sanitary inspectors, 1 per 100,000 population. Few diagnoses of infec-

tious diseases or causes of death are made by qualified medical practitioners.

International Teams

The International Cooperation Administration and U.S. Information Service teams already in Pakistan dropped other duties to combat the epidemics. The ICA teams, six men from U.S. Operations Mission, West Pakistan, and six from U.S. Operations Mission, East Pakistan, concentrated on organizing and operating antiepidemic activities. The five-member USIS team took over health information tasks with the collaboration of the ICA health educator.

The international teams sent to the Province performed a variety of jobs. The nine

Figure 2. Smallpox cases and deaths, East Pakistan, 1958

officers from the Communicable Disease Center, Public Health Service, trained all the public health physicians in East Pakistan in antiepidemic measures, tested the potency of vaccines, investigated outbreaks of cholera, did epidemic surveillance early in the vaccination campaigns, and later evaluated the success of the vaccinating.

The nine-man U.S. Navy medical research team from Formosa set up a laboratory in the Institute of Public Health for the diagnosis of cholera and conducted bacteriological surveys in affected villages. They also evaluated the potency of the vaccines being received and worked on the production of smallpox vaccine in eggs, the production of dry vaccine, and improved methods of vaccine production from cows.

The six members of the team from the U.S.S.R. collaborated in the studies of cholera,

advised the Department of Public Health smallpox, and were interested in testing value of bacteriophage in the treatment prevention of cholera.

The 20-member team from Afghanistan performed vaccinations in the Dacca, Chittagor and Chandpur areas.

Smallpox in the Eastern Province

Epidemics of smallpox have occurred at intervals of a few years in East Pakistan (fig. 3). The epidemics are highly seasonal. Each year the Department of Public Health has made and distributed vaccine and has vaccinated on a large scale. The 5 to 16 million vaccinations reported per year from 1948 to 1957 would indicate that the population had a high degree of immunity. In spite of these reports, a major epidemic occurred.

Figure 3. Smallpox cases and deaths, East Pakistan, 1948-58

The vaccine routinely used was made by the vaccine laboratory in the Institute of Public Health and distributed in small cylindrical bottles stoppered with a cork. The vaccinator "wetted" the cork with vaccine, dabbed the arm, and made a circular scratch with a lancet sterilized in flame kindled by igniting cotton wool dipped in methylated spirits. For a primary vaccination this was done in two places on each arm. The vaccine was said to be potent for 7 to 10 days without refrigeration.

In a small way I checked on this procedure in two suburbs of Dacca, where people had been vaccinated 3 to 7 days before with vaccine kept for a week without refrigeration. Among 129 people, I saw only 2 whose vaccinations were not effective. Both were adults who had been previously vaccinated.

The CDC and the U.S. Navy teams recorded their evaluations of the situation in a series of reports which provide much of the data cited in this paper. In May, the CDC epidemiologists, each paired with a Pakistani doctor who acted as guide and interpreter, visited the various districts to inquire into the morbidity situation and to check the vaccination status. Vaccination rates were estimated by inspecting the scars on samples of the populations. The data had to be collected in great haste and for this reason are not suitable for analysis in great

detail, but nonetheless probably give a fair indication of the true situation. Seventeen percent of the sample group were found never to have been vaccinated, 22 percent to have old scars only, 41 percent to have been revaccinated in 1958, and 20 percent to have had primary takes in 1958. In a population of 46 million, this represents a substantial number of vaccinations.

Generally, the epidemiologists of the team felt that the statistics available on morbidity gave a true picture of the trends, even if the totals were not strictly accurate. They analyzed the number of deaths reported, since this figure was more likely to be accurate than the number of cases reported.

Briefly, they found that most of the deaths were in children under 10 years of age. They also discovered that chances of acquiring smallpox were related to vaccination history. Of 685 patients they studied, 19 had been vaccinated within the past 10 years, 207 had been protected for more than 10 years, and 459 had never been vaccinated.

The geographic distribution of cases was not uniform. The northeastern districts almost escaped the epidemic, the east central ones suffered heavily in 1957, and the western ones had the peak of their epidemic in 1958. In the Rajshahi and Dinajpur Districts, the CDC officers traced the spread of the infection along the railroad.

Vaccinating During the Crisis

After the Chief Minister handed over epidemic control to the citizens committee, local nonmedical groups in every district took over the vaccinating. The medical colleges in Dacca were closed, and doctors and students spread out over the entire Province as volunteer vaccinators. They worked for 2 or 3 months, received only a bare subsistence allowance, and undoubtedly vaccinated many people, 300,000 in Dacca alone.

But their efforts were uncoordinated, and 200 or 300 ardent workers, even with the assistance of official vaccinators and 400 sanitary inspectors, could not protect 46 million people. The average vaccinator, working from house to house and stopping to persuade reluctant people, cannot average more than 100 inoculations

At a roadblock in Comilla all passers-by are vaccinated against smallpox.

a day. Travel on foot between villages and 1- to 3-day trips to and from Dacca lower the daily average substantially.

After 3 weeks of consideration, the Government and the epidemic control committee finally agreed on the following course of action: vaccinate 80 percent of the people within 6 months, stamp out the remaining traces of infection in the next 6 months, enforce the law requiring children to be vaccinated, and attempt to revaccinate the population every few years through an improved health service. The Government also agreed that during the initial phase, 1 volunteer per 1,000 people would be raised and trained through the local committees and that the Department of Public Health would be strengthened in time to undertake the second and succeeding phases.

The Government appealed for these local volunteers, 1 for each 1,000 persons, a total of 45,000. The task was great, but the scheme had the advantage that the people of each village or group of hamlets could be vaccinated by someone who knew them. Traveling expenses for such volunteers would be minimal and much of the resistance, especially from women in purdah, would be overcome. Doctors, students, and sanitary inspectors could instruct the volunteers instead of doing the vaccinating themselves.

By this time in May, more than 3,000 cases

and 1,300 deaths from smallpox and 600 deaths from cholera were reported every week. Already nearly 20 million persons had been vaccinated, and more than a million more were being vaccinated every week, but still this task was not being done quickly enough, and coverage was not sufficient. Therefore, a joint Pakistan-ICA-USIS team planned an additional campaign to cover the Province, district by district, over a 6-month period.

The team began work in the Tippera District. In the subdivision of Comilla they used a bagpipe band from the Frontier Force to attract crowds to the stadium for health shows. Crowds of thousands attended two evening mass demonstrations and a number of enthusiastic youths volunteered to be trained as vaccinators. But the volunteers were of little use; a hundred turned up the first day to do the vaccinating, a handful the next day, and only one on the third day.

Although the operation was a failure in the number of vaccinations performed, the team found out which types of health information campaigns were practical, the willingness of the people to collaborate, the difficulties of travel, the local resources, and the most feasible ways of distributing vaccine and training volunteers.

In subsequent programs, audiences, mostly all male, at the night health shows ranged from 2,000 to 10,000. In Dinajpur the women were persuaded to attend by dividing the field in two with a bamboo fence to separate the sexes.

The teams spent daylight hours meeting with committees, giving speeches over a loudspeaker mounted on a car, and distributing pamphlets. Frequently, as the teams drove along a lonely road bordered by fields of jute or rice stretching for miles, they stopped the cars and blew the horns. At the sound, figures wearing enormous sun hats popped out of the fields of rice or jute and a few started to run toward the car. In 5 minutes a fair-sized crowd assembled to hear a talk on smallpox and vaccination.

Brahmaubaria, another subdivision of Tippera, with a population of 1 million, provided a heartening contrast to the experience in Comilla. The Pakistan-ICA-USIS team could spend only a day there consulting with the subdivisional officer and the subdivisional health officer, a sanitary inspector. These two men

had only a jeep, very little money, and a handful of sanitary inspectors and vaccinators to cover a large territory with few roads. However, they looked for volunteers who were disciplined, intelligent, educated, and available in large numbers. They found them in the school children.

The children easily picked up the vaccination technique from their teachers, who were trained by the sanitary inspectors. The teams of children, supervised by their teachers, worked in the villages around their schools. They did not need transportation and were welcomed by everyone, including women in purdah. When the CDC team made its evaluation a month later, they found that more than 80 percent of the population sampled had been vaccinated.

The successful campaign in Brahmanbaria demonstrated that mass vaccination is not basically a medical undertaking but a layman's job of organization, propaganda, and logistics. In subsequent months this was proved over and over; wherever the administrative officers took personal charge, the vaccinating was effective, but where they were uninterested, the campaigns were failures.

The Vaccine

Most of the vaccine sent to East Pakistan was the lymph type, requiring refrigeration. The Government of East Pakistan requisitioned the only cold-storage facility in Dacca to store it as it arrived by air. Batches packed in dry ice often arrived with the dry ice surviving and, whenever possible, were forwarded with the packing undisturbed to field stations. Some dry ice was still unevaporated when packages reached places a day's journey from Dacca.

According to the manufacturers, the vaccine would remain potent 2 to 3 days without refrigeration, but in our experience, most of it involuntary, the vaccine was effective for a week or more in temperatures of 80°-100° F. The packaging of the vaccine from the United States was bulky; 50,000 doses occupied the same space as a million doses of the local product, and this was a big handicap, for refrigerators were very scarce.

In addition to the vaccine sent to Pakistan,

the vaccine laboratory of the Institute of Public Health obtained an adequate supply of calves and, by May, was turning out 1 million doses a week. A laboratory in Lahore, West Pakistan, supplied 500,000 doses weekly. The U.S.S.R. team suggested two Soviet dry vaccine plants were available should the Pakistan Government wish to accept them. The Navy team made a dry vaccine from a chick embryo growth with an apparatus used by the Department of Agriculture to prepare rinderpest vaccine. The United States, through ICA, offered a dry vaccine plant capable of processing 500,000 doses a week, and the Pakistan Government accepted it.

Dry vaccine remains potent without refrigeration much longer than the wet type, and its advantages where travel is difficult and refrigerators are scarce are obvious.

Vaccination stylets were in short supply, so at first the needles which came with the vaccine from the United States were used with vaccine from other countries. Then the United States team suggested using a large steel sewing needle which would be given to the person who was vaccinated with it. The needles are valued by the people in Pakistan, and their use eliminated channels of cross-infection and the nuisance of sterilizing instruments. In June ICA sent 11 million sewing needles.

The technique of vaccination was streamlined. We stopped swabbing the arm before inoculation because of the shortage of cotton wool and alcohol and no cross-infections were reported. The bandage at the inoculation site was also eliminated. With wet vaccine, the bottle was given a shake and the dampened cork applied to the arm. The dry vaccine bottles lacked stoppers, so the needle was dipped in the bottle and a drop taken out.

The method taught was the multiple pressure technique of vaccinating, but some vaccinators made punctures, some, long scratches, some, elaborate crosshatchings, and some did as they were taught. All methods seemed to work if the vaccine was fresh and potent. In the campaign we accepted no contraindications to vaccination, for the risk of infection was too great.

The diversified sources of the vaccine gave us a chance to compare the potency and various

fashions of packaging. The Navy team has reported on comparisons of potency.

For vaccine to be used under conditions similar to those in East Pakistan, the following requirements are recommended for convenience in handling. The vaccine should be dry. Each ampoule or bottle of vaccine should contain about 1 day's supply, approximately 100 doses. The bottle should be sturdy, flat bottomed so that it can stand alone, and have a mouth wide enough to make the transfer of the diluent easy.

The diluent containers should not be stoppered with corks or screw tops which leak during shipment by air. A minimum of glass-cutting should be required to open them. The device holding the stopper in place should be simple to remove. The fluid should be transferable without syringes or pipettes.

Bottles for the reconstituted vaccine should have stoppers which can be used as applicators. Special applicators are easily lost. Some substance should be added to prevent growth of contaminating bacteria.

The instructions and the expiration date with the name of the month, rather than the number, should be written in a language familiar to the person using the vaccine. The expiration date should be on each bottle. The package containing the bottles should be strong, easy to open, and include all essential items so that it is ready for distribution.

The Cholera Epidemic

In East Pakistan cholera appears in dry weather, reaches a peak in May, and disappears with the first rains. The Province normally has several hundred deaths from cholera each week in May (figs. 1 and 4).

The vaccine in present use requires two injections of 0.5 ml. and protects only for 6 months, but in India, it is customary to give one dose of 1.0 ml. Semiyearly immunizations were simply not practical in East Pakistan.

Although many inoculations were given, the Department of Public Health concentrated on distributing drugs to treat cholera. However, medical staffs are spread very thinly over the Province and transportation for them or for patients is scarce. A trip to a hospital might

mean carrying a patient many miles by bullock cart over the rice paddies, so that the chances of a patient being seen by a medical person were very small. In the middle of the outbreak, a visit was paid to the cholera ward in Barisal, which was found empty, although stricken villages were reported from all sections of the surrounding district.

The Department of Public Health sent mobile teams to affected villages, but since reporting of the outbreaks took several days, the patients were either dead or convalescent by the time the teams reached them. Often, many people in a village became ill at once; a week or 10 days later another village some distance away would be stricken.

Cholera reporting since 1948 appears to be inadequate; cases about equaled deaths, although in 1958 the fatality rate was 40 percent.

Diagnosis can be difficult and in 1958, physicians called almost every case of diarrhea a case of cholera. The U.S.S.R. and Navy teams studied cases in hospitals and concluded that perhaps 50 percent of the cases in the cholera wards were due to other infections.

Both teams had difficulty finding fresh cases; patients admitted to the hospitals were convalescent and had already been treated in a variety of ways. The Navy team isolated *Vibrio cholerae* from nine patients in a cholera ward and five apparently healthy contacts in a Dacca

Figure 4. Cholera cases and deaths, East Pakistan, 1948-58

suburb. The isolates had these characteristics in common: they fermented sucrose and mannose but not arabinose, were positive in the cholera red test and negative in the Voges-Proskauer and hemolysis tests, and serologically were of the Ogawa type.

Preventive measures against cholera in other countries depend on safe water, good hygiene, and efficient sewage disposal. The Pakistan Government, with ICA help, is trying to provide piped water in the larger towns, large-bore tube wells in the smaller ones, and smaller tube wells for the villages. However, it may be 10 years before the general population has wells and the average villager is persuaded to abandon his tank for washing and drinking water.

Epidemiology of Cholera

Bengal has the unenviable distinction of being the home of cholera and quite possibly is the only place on earth where the infection can exist all year round decade after decade. Cholera is endemic only in Asia. The U.S.S.R. team, which had been operating in China, stated that all the epidemics in the U.S.S.R. and China were imported from outside those countries. In the Indian subcontinent, the disease is found all year round only in Bengal.

Cholera first appeared on record in severe epidemic form in 1817 in the Calcutta area. Four times in the 19th century it appeared in a series of waves around the world, and these major pandemics were traced back to Bengal. There are possibly smaller foci elsewhere in southeast Asia, but the Bengal area, which the 1947 partition divided between India and Pakistan, is the only major endemic focus. If cholera could be eliminated there, it seems likely that it would disappear entirely from the world. However, the epidemiology of the disease has not been worked out completely, although obviously it is associated with unhygienic conditions.

Why is cholera endemic in so limited an area? A possible answer lies in the nature of the country—the flat, waterlogged land, the dry season and the monsoon season, and the water tanks which are centers of community life. The paths of spread of the cholera pathogen in an average Bengal village are numerous, but all

are insignificant compared with the massive potentialities of these tanks.

The distribution of cholera in East Pakistan supports the theory that the tanks are related to the maintenance of the infection. In the northern districts and the higher areas where tanks are not so common, cholera apparently occurs only during the epidemic dry season. In the low southern districts, where tanks surround every hamlet, the disease persists year round.

Traditionally, cholera disappears in Bengal with the onset of the monsoon. During the 1958 monsoon season outbreaks of cholera reported in Noakhali and Faridpur, upon investigation, seemed to be genuine, indicating the infection to be endemic there in spite of the monsoon. With the appearance of the dry weather in October 1958, the cholera soon shot up alarmingly to a maximum of 700 cases a week, but the rains in January 1959 were heavier than usual, and almost immediately the cholera dwindled. In February 1959 a local epidemic in Comilla occurred, but following some unseasonable rains, the disease again disappeared. In March the whole area had heavy rainfall and the cholera sank to an extremely low level for this time of year.

V. cholerae, recently isolated, can grow in a decidedly alkaline media. It is difficult to concede that this unusual cultural requirement is purely nonadaptive, so it is natural to look for some environment where the pressures of natural selection result in the production of such a characteristic.

One can speculate on these facts. If the tanks are the basic reason the infection is localized to Bengal, the disease spreading from there to other parts of the world, then possibly changes in the alkalinity of the water in the tanks might account for epidemiological differences between the dry and wet seasons as well as the requirements of the organism. Perhaps the first rains stop the main avenue of transmission by altering the pH of the water in the tanks.

Studies are in progress to see if there is a positive correlation between the pH of the tank water in different periods of the year and the incidence of cholera. Preliminary studies in the dry season have already shown that tank

A physician from the Communicable Disease Center and his companion, a Pakistani physician, prepare to give inoculations against cholera.

water commonly has a pH much in excess of 8, which would favor the cholera organisms. Following a few days of dry weather, the pH before dawn is between 7.0 and 7.5 and by evening can be as high as 9.5 or 10.0. It is known that pH in such waters is largely dependent on the activity of algae that produce either oxygen or carbon dioxide according to the degree of light available, and that considerable changes take place between night and day. The rainfalls theoretically could reduce the pH both by the clouds reducing the sunlight and, even more, by dilution or making the water muddy. During the dry season, all ponds become almost saturated with algae. On rainy days, the pH does not commonly rise above 8.4, the optimum for *V. cholerae*. If it should be proved that the pH is altered markedly by the monsoon or heavy rains, a reasonable explanation can be given for the known facts of the epidemiology of the infection as well as the cultural requirement of the organism.

Whether cholera has long-term carriers is not yet clear. The Soviet team said they had found

people excreting organisms for 2 months and in one instance for 1½ years. However, it is difficult to test the pathogenicity of organisms recovered from carriers. It would not be necessary for carriers to excrete organisms for more than 3 months for the organism to survive permanently in south Bengal.

At present, hope of controlling and eradicating cholera depends on providing safe drinking water and convincing people of the importance of hygienic measures. Immunization is a weak barrier and the value of bacteriophage remains unproved. In East Pakistan the trend of the disease is downward (fig. 4), which gives hope that environmental changes might be leading to its extinction.

Epidemiology of Smallpox

Smallpox in southeast Asia was clearly described by Chinese writers 4,000 years ago, and, according to 3,000-year-old scripts such as the Susruta, Indian Ayurvedic physicians were also familiar with it.

The history of smallpox in East Pakistan is marked by substantial epidemics which last for about 3 years, recurrence at intervals of 5 or 6 years, and seasonality. Substantial 3-year epidemics occurred in the early 1940's, the beginning of the 1950's, and in 1957-58. Smallpox is a disease of the early months of the year. Its Bengali name, *basanta*, means "the spring-time."

The apparent explanation of the recurring epidemics is that smallpox is following the same cyclic type of pattern as measles in the Western countries. An epidemic leaves few susceptibles so that another cannot occur until a fresh crop of susceptibles appears. This concept is supported by the fact that most deaths are among children under 10 years of age, and 40 percent of the mortality is among those under 5 years.

But the matter is not so simple. Even in the worst epidemics in East Pakistan, the total number of cases is under 100,000 a year, while the babies born each year are counted in millions. For the infection to immunize enough people during an epidemic to produce a cyclic pattern, a considerable number of inapparent

infections would have to be postulated for each case of smallpox.

This happens in many other infections but, as far as I know, it has not been demonstrated in smallpox. However, the fluctuations in the immunity status of the population necessary for cyclic epidemics are probably provided by other factors, the vaccinator and his vaccine.

Each year millions of vaccinations are performed by the public health services, but the number depends on the epidemic conditions of that particular year. Ten million persons may be protected if there is an epidemic scare but only 2 or 3 million in nonepidemic years. Immunity given by vaccination in step with the epidemics may produce the cycles that are so prominent in East Pakistan.

Smallpox is easy to prevent; vaccination is simple and can be done by illiterate people. The vaccine is cheap and can be mass-produced. It should be possible for each country in southeast Asia to vaccinate 90 percent of its people within a year and to repeat the operation every 3 to 5 years. The resulting level of immunity would probably cause the disease to disappear completely.

FDA Warning on Irregular Use of Diabetes Test Papers

The use of certain chemically treated diabetes test papers by women to determine the fertility cycle may be injurious, according to the Food and Drug Administration. Some of these test papers contain the chemical toluidine, which has not been adequately tested for its effects on the sensitive tissues of the female reproductive system.

The papers are marketed for use by diabetics, who are able to determine the presence of sugar in the urine by moistening the paper with a small amount of urine. The chemically treated papers change color if sugar is present. No question has been raised about the safety of this procedure for diabetes.

It has been reported, however, that the secretions of the cervix also contain enough sugar during the ovulation period to cause the test paper to change color. This has resulted in publicizing the use of test papers for determining the fertile period of the menstrual cycle.

The Food and Drug Administration emphasized that the use of the chemically treated papers to determine the fertility cycle should be discontinued until appropriate tests have shown that the procedure will not cause injury to sensitive tissues.

The Feasibility of Smallpox Eradication

GLENN S. USHER, M.D., M.P.H.

IN JUNE 1958 the World Health Organization gave consideration to a proposal that it undertake a worldwide smallpox eradication program. The proposal was approved in principle, and the Director General was instructed to study the feasibility and possible means of accomplishing the task.

WHO's action lends timely interest to smallpox control experiences such as a group from the Communicable Disease Center of the Public Health Service had in the spring of 1958 in East Pakistan. This Province, formerly known as East Bengal, has long been known as a stronghold of smallpox and a place where control efforts are beset with difficulties as great as any to be found in the world. If eradication of the disease is feasible in the circumstances presently existing there, it should be feasible anywhere.

The occasion for the CDC team's trip was a smallpox epidemic of alarming proportions. Many countries, including the United States, extended assistance in combating both this epidemic and a cholera epidemic that was raging concurrently. U.S. assistance was coordinated by the International Cooperation Administration's Mission in East Pakistan under the direction of Dr. Thomas A. Cockburn, ICA's public health adviser in Dacca.

This team reported to Dr. Cockburn and with him to the Minister of Health and Home Government of East Pakistan. It was assigned the task of serving as the "eyes and ears" of the smallpox control campaign with the following duties:

Dr. Usher is special assistant for medical activities, Communicable Disease Center, Bureau of State Services, Public Health Service. He was co-leader of the CDC epidemic aid team in East Pakistan, May-July 1958.

1. Study the history and characteristics of smallpox epidemics in East Pakistan and the various related factors.

2. Define the nature, extent, and distribution of the smallpox epidemic.

3. Assess the resources that could be brought to bear on the control of the epidemic and the obstacles to be overcome.

4. Evaluate the current control campaigns in the districts and identify areas of success and failure.

5. Identify, in cooperation with Pakistani health personnel, epidemiological factors of importance to the smallpox control program.

In the execution of these duties the need to obtain data that would be as nearly representative as possible of the entire Province led to field trips to all 17 of its districts. Team members traveled by airplane, train, river steamer, jeep, oxcart, rickshaw, "country boat," and on foot. On most trips each of us was accompanied by a young Pakistani physician who had volunteered his assistance. The associations with these dedicated young men turned out to be most rewarding both to them and to us.

It is not the purpose of this paper to describe the control campaign that was conducted or the activities of the team. Some of our observations, however, are pertinent to the question of whether it would be feasible to attempt eradication of smallpox in East Pakistan at this time, and what would be required in order to achieve this goal.

Two Crucial Factors

The history of smallpox in Bengal and East Pakistan may be seen at a glance in figures 1 and 2. For as far back as records have been kept, the disease has occurred in cyclic waves. Figure 1 illustrates these cycles for the period 1912-46 in all of Bengal prior to the 1947 par-

tition. Figure 2 shows the smallpox deaths in East Pakistan from 1948 to 1958.

From these data may be derived the first crucial factor of the problem: smallpox is deeply entrenched in East Pakistan as an endemic and epidemic disease. Despite the fact that much vaccinating has been done (small sampling surveys performed by the team demonstrated that 60 to 90 percent of the population had been vaccinated), epidemics continue to recur in cyclic waves.

The other crucial factor of the situation is the extreme density of the population, which obviously must have great significance in maintaining the endemicity and epidemicity of the disease. With 45 million people crowded into a land area slightly smaller than the State of Illinois, the average population density is 777 persons per square mile.

"Density of Susceptibles" Concept

The significance of East Pakistan's great population density is demonstrated by the team's study of the manner in which the 1958 epidemic developed and peaked.

This epidemic was not a sudden occurrence. Although figure 2 shows the increased incidence for the Province as a whole starting in 1956, reports by district that were available to the team showed that the increase in Dacca started as early as 1955. From that year until 1958 there was a gradual buildup of the epidemic. Dacca and Tippera Districts are the most populous of the Province's 17 districts, with population densities of about 1,500 persons per square mile.

The appearance of conspicuous numbers of smallpox deaths in Dacca District was followed by similar occurrences in 1956 in Tippera District and in a few of the other more populous districts. The peak of the epidemic was reached in Dacca, Tippera, and two other districts in the spring of 1957, a full year before the peak of the epidemic in the Province as a whole. Conversely, the most sparsely populated district, Chittagong Hill Tracts, remained essentially epidemic free throughout the entire period. Only a few sporadic deaths were reported in 1958.

The team made a few samplings of the vacci-

Figure 1. Deaths per 1,000 population from smallpox in Bengal, 1912-46

Figure 2. Deaths from smallpox in East Pakistan, 1948-58

nation status of the people in most of the districts, as evidenced by the proportion of persons having vaccination scars. On the basis of these surveys, the team made some very crude estimates (the best we could do in the available time) of the proportions of the district populations that had been vaccinated. These estimates ranged from about 60 to 90 percent (including old vaccinations), but we were unable to find any correlation between the proportion of the population that had been vaccinated and either the time of onset or the intensity of the epidemic in various districts.

As a result of the observations described in the preceding three paragraphs, it was the team's impression that, within this 60-90 percent range of proportions of persons vaccinated, both the time of epidemic onset and the intensity of the epidemic were more closely related to population density than to vaccination status. This conclusion leads to the suggestion that the density, that is, the number per square mile, of unvaccinated persons would be a better index of the susceptibility of East Pakistan's dense population to a smallpox epidemic than the index that is ordinarily used, the proportion of the population that has been vaccinated.

This, of course, is the well-known concept of the density of susceptibles. It should be useful in identifying sections of the country where vaccination campaigns need to be intensified.

Age, Sex, and Social Groups

Although the density of susceptibles is believed to be a better indicator than the proportion of vaccinated persons, it is admittedly only a crude index of the vulnerability of a population to smallpox epidemics. Obviously of great importance also is the uniformity of distribution of susceptibles among various segments of the population, such as age, sex, and social groups. If there are excessive numbers of susceptible persons in one or more of these population segments, their excessive vulnerability would be expected to result in a greater degree of vulnerability of the total population than the mean density of susceptibles would indicate.

In the East Pakistan epidemic we found that children under 10 years of age were not as well vaccinated as older age groups. This fact was reflected in the age distribution of cases and deaths (table 1). It was clear that special attention needed to be given to improving the vaccination status of children.

Table 1. Age distribution of smallpox cases and deaths in Mitford Hospital, Dacca, and in selected districts, East Pakistan, January-May 1958

Age group (years)	Cases			Deaths				
	Mitford Hospital	Pabna District	Total	Mitford Hospital	Tippera District	Faridpur District	Dinajpur District	Total
0-1	4	49	53	2	34	16	37	89
1-4	32	245	277	17	199	122	236	574
5-9	32	209	241	12	121	125	152	410
10-14	25	77	102	11	19	26	22	78
15-19	21	32	53	10	21	16	12	59
20-29	63			24	43	53	11	131
30-39	27			9	33	44	10	96
40-49	15	307	422	4	32	30	8	74
50-59	6			2	36	17	2	57
60 and over	4			2	36	11	1	50
Total	229	919	1,148	93	574	460	491	1,618

Since Moslem women of Pakistan are in purdah and consequently lead a secluded life, the team expected to find substantial differences in the vaccination status and prevalence of the disease in the two sexes. This, however, did not turn out to be the case. Sampling surveys revealed approximately equal proportions of unvaccinated persons in males and females. Table 2 shows that in the areas studied, except for Mitford Hospital, the male and female cases and deaths were approximately equal. (Field observations failed to lend credence to the suspicion that the seclusion of women might result in their cases and deaths being less well reported than those of men.)

Table 2. Sex distribution of smallpox cases and deaths in Mitford Hospital, Dacca, and in selected districts, East Pakistan, January-May 1958

District	Males		Females	
	Cases	Deaths	Cases	Deaths
Mitford Hospital, Dacca	142	57	87	36
Noakhali	350	82	417	98
Pabna	478		441	
Dinajpur		217		244
Faridpur		238		222
Total	970	624	945	600

The many religious sects and social groups of East Pakistan have sharply contrasting customs and habits of social behavior. Time did not permit a comparative study of the occurrence of smallpox in them and its relationship to population density and vaccination status. However, in conversations with local health officials the CDC team learned that some groups had responded poorly to vaccination campaigns and experienced high smallpox attack rates. Vaccination programs need to be intensified in localities where these groups reside.

From Control to Eradication

It has been said that when vaccination of 80 percent of the population has been achieved, smallpox will die out. In our opinion this is an oversimplification. In the more densely populated parts of East Pakistan it seems likely that a substantially higher percent of recently vaccinated persons would need to be achieved in order to eradicate smallpox by mass vaccination alone, and that this vaccination status would need to be maintained for several years.

Because of the extreme difficulty of accomplishing this in a country like East Pakistan, the surveillance phase of the eradication program should be introduced at an early stage—as soon, in fact, as the incidence of the disease has been reduced to a level where it becomes feasible to undertake emergency containment of each small outbreak as it occurs. Initiation

CDC Team

Members of the Communicable Disease Center team who participated in the collection and analysis of the data referred to in this paper were, in addition to Dr. Usher, Dr. Alexander Langmuir, chief, Epidemiology Branch of CDC; Dr. Frederick L. Dunn; Dr. Jacob A. Brody; Dr. Malcolm I. Page; Dr. Chandler R. Dawson; Dr. James W. Mosley; Dr. W. Yates Trotter; and Dr. H. Bruce Dull.

of this phase of the program should be timed to take advantage of the low incidence of an interepidemic period.

This is the manner in which smallpox was eradicated in the United States. Although it apparently was not accomplished by following a consciously conceived plan, what happened was that in the relatively sparse population of the United States it proved to be possible to reduce the density of susceptibles, and consequently the incidence of the disease, to a very low level by the vaccination of a smaller proportion of the population than would be necessary in East Pakistan. Thereafter it became possible to regard the occurrence of a case of smallpox as an emergency calling for immediate vaccination of the entire community. An especially dramatic example of this was the 1947 incident in New York City when the recognition of 12 cases of smallpox led to the vaccination of some 7 million people within a month.

In the surveillance or "firefighting" phase of an eradication program selective vaccinating of exposed persons (sometimes referred to as "ring containment") is, of course, desirable, but it is not considered advisable to rely entirely upon this for the emergency containment of outbreaks. This is especially true in a country like East Pakistan where health services are not fully developed, and there is a shortage of qualified health personnel for the performance of contact investigations. In such circumstances it seems essential to rely primarily upon "area containment," that is, an immediate, very intensive campaign to raise to the highest possible level the vaccination status of a community where an outbreak has occurred.

The successful execution of the "firefighting" phase of the eradication program in a country where the problem is as difficult as it is in East Pakistan may require rather drastic measures, such as area quarantine, during the time required to vaccinate a community in which an outbreak has occurred. Enforcement of emergency measures will need to be determined and persistent.

Is It Feasible?

Although the required strategic concept is simple and the technical procedures are not complex, the successful implementation of such a program in East Pakistan will not be easy. Traditionally, intensive vaccination activity there occurs only during epidemics. In inter-epidemic periods vaccinations continue at a more leisurely pace. To continue intensive vaccination activity when an epidemic is not raging would require understanding and sustained support by officials in the highest levels of the Government who have the responsibility of appropriating the funds to keep the work going. Furthermore, when it becomes necessary to apply drastic measures in the second phase of the program (the firefighting phase) there must be public understanding of the need for them.

Difficult problems of logistics also are involved. Transportation and communications facilities in East Pakistan are very poor. Personnel engaged in this program would need to be given priority use of those that are available, and funds are needed for purchase and repair of vehicles.

Where wet lymph is used, additional and improved facilities are needed for its refrigeration right up to the time when it is used in order to maintain its full potency. In some isolated sections of the country it seems essential that dried vaccine be used and perhaps consideration should be given to using dried vaccine exclusively. Whatever type of vaccine is used, it is essential that it be packaged in such a manner as to permit its satisfactory use by nontechnical personnel with little manual dexterity. For example, it is impractical to use a vaccine packaged in a vial that requires filing off a glass tip.

These are the requirements that appear to be crucial. The CDC team arrived at the opinion that the problems, although difficult, are not in-

surmountable. Eradication of smallpox in East Pakistan will be a difficult task, but it is considered feasible to undertake it at this time.

Summary and Conclusion

A proposal that the World Health Organization undertake a program of worldwide smallpox eradication is under study at the present time. The feasibility of such an undertaking under presently existing circumstances is dependent on the likelihood of success in countries where eradication is likely to be most difficult to accomplish and the obstacles greatest. One of these countries is Pakistan, in whose Eastern Province smallpox is deeply entrenched as an endemic and epidemic disease.

In 1958 a team of epidemiologists from the Communicable Disease Center of the Public Health Service was assigned to the International Cooperation Administration to participate in the assistance that the latter was extend-

ing to the Government of Pakistan in combating a smallpox epidemic in East Pakistan. Some of the observations of this team are pertinent to the question of whether it would be feasible at this time to attempt the eradication of smallpox in the Province.

It is concluded that such an undertaking is feasible at this time if certain problems are recognized and successfully dealt with. The concept of "density of susceptibles" is postulated, and certain other factors bearing on the problem are discussed. It is suggested that the strategic plan would need to be the same one that has led to the eradication of smallpox elsewhere, namely, reduction of prevalence by means of widespread vaccination, followed by surveillance and emergency containment of each outbreak as it occurs. For the latter it is believed that primary reliance should be placed on "area containment" rather than "ring containment."

Conservation of Air Resources

FRANK TETZLAFF, M.C.E.

AIR POLLUTION has been defined as the presence in the air around us of substances put there by the activities of man in concentrations sufficient to interfere directly or indirectly with our comfort, safety, or health, or with the full use and enjoyment of our property (1). In many communities the simultaneous outpouring of many particles, fumes, dusts, vapors, gases, and ash, and the subsequent interactions of these pollutants in the atmosphere have created prolonged irritative effects on people; damaged vegetation, livestock, and structural and other materials; decreased visibility, with hazards to air and ground transportation; and impaired property values. Estimates of the probable cost to the communities of some of these effects have ranged from \$10 to \$65 annually for each person (2). But large as this figure may seem, it still does not include the cost of esthetic deterioration, the damage to the general fitness of the environment, and the desirability of the community as a place to live, to all of which it would be difficult to assign a dollar value.

The communities in the United States with long-established smoke abatement programs are relatively few. Many such programs have only recently begun, notably with the industrial and community expansion emerging during World War II. The U.S. Bureau of the Census statistics show that the growth of metropolitan areas

in the United States has crowded over one-half of our present population of more than 175 million into some 180 metropolitan areas, less than 10 percent of the land area. The tendency to urbanization will continue, with further complications of air pollution.

No single factor can be charged with full or principal responsibility for air pollution. Many common and essential activities contribute. While automobile exhausts may be significant in one community or in one part of town, industrial fumes and vapors may be disturbing elsewhere. In many large cities, garbage and refuse incinerators in apartment houses or even backyard incinerators have been major contributors. Municipal incinerators, powerplants, steel mills, ore smelters, and petroleum refineries are serious sources when improperly operated or lacking devices to control dust, smoke, or other discharges. Certainly operations such as the burning of open garbage and refuse dumps and the uncontrolled burning of automobile bodies in metal salvaging operations are offensive practices.

Although the effects of air pollution are generally subtle and difficult to measure, they can be apparent and even disastrous (3, 4).

The growing concern with air pollution has resulted in Federal legislation authorizing the Public Health Service to conduct a program of research and technical assistance (5). Since efforts to control air pollution have been hindered by the lack of technical knowledge concerning the causes, effects, and practical control measures, major emphasis has been placed on research.

In developing air pollution research, the Public Health Service has enlisted the aid of other Federal agencies, universities, and research in-

Mr. Tetzlaff is chief, Air Pollution Engineering Branch, Division of Engineering Services, Bureau of State Services, Public Health Service. This article was excerpted and updated from a paper presented at the annual convention of the General Federation of Women's Clubs, held in Hollywood, Calif., June 5, 1959.

stitutions in every part of the country. Some studies are designed to determine which air pollutants, if any, cause or intensify specific disease conditions or otherwise adversely affect the population (6). Through such studies, we may learn what pollutants must be removed from the air and what elements may be safely ignored. By observing the effects of polluted air in the laboratory and on human beings over a considerable period of time, sound conclusions can be reached. Significant leads have been uncovered. There is evidence of a relationship between air pollution levels and mortality rates from stomach and lung cancer, with allowance being made for smoking habits (7). We know that there are pollutants in urban air which can produce cancer in experimental animals.

A followup study on the population of Donora, Pa., has shown that the people who were made ill by the air pollution disaster in 1948 have had poorer health in general and higher mortality rates these past 10 years than their neighbors who were apparently unaffected. Many who died during acute air pollution episodes in London, Donora, and the Meuse Valley were elderly people with preexisting respiratory or cardiac difficulties.

Research in Great Britain has shown a direct relationship between air pollution and chronic bronchitis, a serious disease ranking third among causes of death in England and first among causes of economic loss due to illness (8). We have reason to believe that chronic bronchitis is also on the increase in this country (9).

During the past 4 years, the Public Health Service has established a national air-sampling network which for the first time permits a systematic measurement of air pollution throughout the United States. At present, the network consists of some 230 sampling stations, all manned by cooperating State and local agencies.

New methods of analyzing pollutants have been developed including the use of chemical, physical, and biological means which are proving to be more accurate and economical. Air pollution effects from specific industrial or community activities, such as oil refining, burning of municipal wastes, and operation of motor vehicles, are being evaluated. Fundamental studies are being conducted of the re-

lationship between weather conditions and the buildup of pollutants in the atmosphere. A method is being developed for forecasting weather conditions which permit the abnormal concentration of pollutants.

An automobile exhaust test facility developed by this program is becoming recognized as one of the best in the country. It permits simultaneous study of divers factors concerned with fuel and engine variables as they relate to the effects of irradiated auto exhaust on plants and animals.

For work on air pollution, short-term training courses are being given for personnel in health agencies. In addition, grants-in-aid have been made to 10 universities for the development and support of graduate level courses. Technical assistance on specific air pollution problems has been provided to State and local government agencies and other organizations.

Congress, in passing Federal legislation on air pollution, reserved to the States and local communities the responsibility for controlling air pollution within their jurisdictions. With the growing interest in conserving the Nation's air resources, States and communities have been surveying their air pollution position. Within the last 10 years, more than 20 States have adopted or modified legislation in this field. An increasing amount of legislative activity has also been observed in municipalities.

No modern city can hope to be completely free of air pollution. Industrial activities necessarily produce vapors, dusts, or gases which slip by the most effective control and retention devices now known. To require industry to establish absolute restraint of such byproducts can easily impose an intolerable economic burden.

There is a need for health agencies to determine the maximum concentrations of pollutants permissible and to apply these standards. This degree of control undoubtedly will prove costly, but it is no longer a question of whether we can afford to conserve the air. We cannot afford not to. It is the breath of life.

It is for this reason that continued research into the effects of air pollution is so vital. New knowledge may show that the application of controls which on the surface appear expen-

sive may actually save as yet unmeasured costs of damage to life and property caused by air pollution.

Status of Public Health Officials

BY UNANIMOUS VOTE, members of the Health Officers Section of the North Carolina Health Association, in Winston-Salem, September 24, 1959, changed their name to the Health Directors Section, with the aim of shedding traditional association with the policeman's club. Modern public health practice, it was argued, thrives best under the glow of the educator's lamp.

As to the standing of health officials in the eyes of their associates, the medical societies, and the general public, however, there was no such unanimity. Members of a panel discussion on this subject disagreed pointedly as to the actual status of health officials, and the audience shared in an amiable controversy over steps which improve status.

With Dr. Arthur S. Chesson, Jr., health director of Wayne County, as chairman, the panel was composed of Dr. Edward G. McGavran, dean of the School of Public Health, University of North Carolina; Dr. M. B. Bethel, also with the school of public health, formerly health director at Charlotte; and Dr. R. D. Higgins, director of local health services for the North Carolina State Board of Health at Raleigh.

While admitting doubts that status can be objectively measured, Dr. McGavran suggested such indicators as the per capita budget for public health programs, expressed in uninflated dollars, relative to past budgets and to other current expenditures; the number and quality of applicants for positions in public health; and the extent to which the department holds or gains responsibility for community services. By such indicators, he said, the status of health officials has been on the downgrade. Per capita

budgets in constant dollars, relative to total national outlays, have been declining. Recruitment has been difficult, he said, although, at the same time, the shortage of personnel has failed to raise salaries as much as in other callings. And many community services associated with public health have been assumed by other departments of government.

Granting that "there is not a finer, more dedicated body as a whole than the public health profession," credited with achievements against great odds, he concluded nevertheless that still greater efforts were needed. While public health officials may enjoy high standing as individuals, he cautioned that the future status of the public health officer was precariously balanced.

To some extent, the dissent from this appraisal related to a definition of status or prestige. Applying the indicators used by Vance Packard as symbols of social status, Dr. Higgins ironically advised the audience to "be a supreme court justice or, as a second choice, a physician specialist; buy an expensive house in the best neighborhood away from the business section; drive a Cadillac or a foreign sports car; be gentle and Episcopalian; wear conservative clothes at work and sports clothes after work; buy clothes at the most expensive store in town and be casual about paying for them; arrive at work either earlier or later than other employees; and in your office have wall to wall carpeting, a private washroom, and an expense account that permits you to take your wife on business trips." By such standards, he observed, social status is appraised.

More seriously, he suggested that standing in the community depends on the amount of

Ne. State Medical Association
and Cooperating Organizations
Dear Friends:

I just wasn't satisfied till I wrote you a few lines to let you all know that I certainly appreciated having an examination for Diabetes at the Nebraska State Fair, it was the first examination I ever had and I just thought it was all wonderful. Could not be any better. I been wanting to take an examination at your Fair for the last 3 years but I always got sick and fainted before I even got started. But this year on Tuesday afternoon Sept. 8 I walked into your Hall

(Two)

of Health, wasn't even expecting on trying any more, but one nice little nurse came along and after she talked to me for about $\frac{1}{2}$ hour she finally talked me into having the examination made, said she would take me through and guarantee I would not faint, so I finally gave in to her. I just simply put all my confidence in her and let her be my guide. She took me through and it didn't seem to bother me one bit. I never thought it could be done

"it was all wonderful"

The letter above is a fair example of the personal appreciation which many feel for public health services. The appreciation of this writer, who confirmed his feeling with a cash contribution, was acknowledged both by the Nebraska State Medical

Society, to which it was addressed, and the Nebraska Department of Health, which cooperated in the exhibit of the Hall of Health. In evaluating health services, the number and character of such letters can be considered along with budget statements, tables of organization, and morbidity rates.

intelligence and knowledge which the job demands and which the jobholder applies. He advised that it is only proper that the jobholder be paid in proportion to the service: the pay is an indicator of the value of the service. Also the authority and responsibility in the job, as it exists in reality rather than on paper, is an indicator of the incumbent's standing. Further evidence of the individual's standing, he said, is seen in the ability to enter into

the circles of power in the community and to influence the decisions of such circles. Most important of all, however, he listed public knowledge and appreciation of the importance of the individual's achievements. Given the achievement, he indicated, the outer symbols of status, such as salary, power, and influence, depend on the extent to which the public understands what has been achieved.

Panel members agreed that efforts which im-

prove standing with the staff, the professional fraternity, or the general public all work in the same general direction, but each undertook to deal with these circles of responsibility separately. The health director's prestige with his own staff, said Dr. McGavran, depends to a considerable extent on actions which show a sincere, personal interest in staff members and their families. He said if an administrator puts concern with the staff first and the job second, staff morale will make the job more effective. He also said that it is only sound practice to help staff members to improve themselves and to gain better positions according to their abilities, rather than to try to hoard valuable personnel.

Equal status of all professions on the staff, rather than a pecking order, he proposed, is a major element in staff performance and prestige of health directors. It is the only way, he said, to get the best use of the best brains, and he advocated weekly, well-planned staff meetings as a means toward this end. As generally acknowledged top banana, he said, the medical officer is in a strategic position to encourage professional equality.

In line with this principle, he urged that administrators not attempt to direct performance in specialties outside their own. "The medical officer is responsible for what the staff does," he said, "not how it is done." Given such responsibility, he said, the staff will demonstrate its superior competence and the health director rises in everyone's estimation.

As to standing in the professional fraternity, Dr. Bethel urged public health officials to increase their communications with their confreres. "Visit, write, or call," he urged. Failure to be in touch, he said, means to lose touch. The mere presence at a meeting, the act of communication in itself, he said, is valuable.

Of even greater value, he said, is mastery of the information which a health official is expected to possess. Questions as to population, hospital and other health resources, morbidity and mortality rates, sanitary conditions and techniques, immunological status, and career opportunities which come chronically in the direction of the health officer should be met with

immediate and authoritative answers. "If you would grow in the eyes of your medical confreres," he told the assembled physicians, "know more than they can possibly know about your business, nor do you fail to show it. We have a utilitarian device in board certification, and it is a solemn duty . . . in the advancement of public health to attain this specialty status," he said. Above all, he said, consult with other professionals on public health programs. "Established doctors," he said, "can give you sound advice that will enable you to fight and slash your way out of many a crude entrapment, and at the same time they will think you a pretty smart fellow for asking their opinions."

At the same time, he cautioned public health officials against asserting knowledge in the provinces of other specialists. "They don't expect it of you and might even decry your shameless effrontery if you are provocatively knowledgeable in their fields, particularly if you are demonstrably deficient in your own."

All members of the panel agreed that it is essential to be alert to community health needs and to study these needs by utilizing the best intelligence available. They were unanimous also in their endorsement of continuing professional education, whether in formal courses, at professional meetings, or through literature, utilizing available consultants and in turn helping others to develop their own professional skills.

They were agreed that a concern with specific health needs of the community at large, so manifested that health services will be sought rather than peddled, is a distinguishing mark of the successful health department. "For example," said Dr. Higgins, "compare the program largely content with responsibility for communicable disease control with one which assumes responsibility for dealing with chronic ills, mental health, and urban growth."

The major ingredient of Dr. Higgins' prescription, however, was his emphasis that the public is an essential channel in the process of exchange of scientific information. "Carefully planned public relations and education," he said, "are needed if the knowledge gained and used is to be adequately supported."

*By Arthur S. Flemming, Secretary of Health,
Education, and Welfare, November 9, 1959*

Amphetamine Drugs

A CRACKDOWN by the Food and Drug Administration against the bootlegging of amphetamine drugs, the initial phase of which has just been completed, has disclosed a serious breakdown in our system of marketing controls for these drugs.

Concentrating initially on the bootlegging of amphetamine to truckdrivers, Food and Drug Administration inspectors obtained evidence that more than 200 operators of truck stops and similar establishments were selling the tablets.

In a number of instances, the inspectors also were able to learn where operators of the truck stops obtained the drugs, and as a result several wholesale peddlers of the tablets are under arrest and are being prosecuted by the Department of Justice.

Criminal proceedings also will be instituted against operators of the truck stops and other establishments found to be selling the drugs unless they are able to show cause why they should not be prosecuted.

In order to obtain this evidence, Food and Drug Administration inspectors have had to maintain various poses, often at considerable personal risk, in order to gain the confidence of truck stop operators, truckdrivers, and others associated with the sale of the tablets.

Agents of the Department of Justice who made the arrests found more than 800,000 amphetamine tablets in the hands of the wholesale peddlers, one of whom alone had 625,000 tablets in his house.

Commissioner of Food and Drugs George P. Larrick and his associates are convinced that the roundup of violators, successful as it was, has only scratched the surface of the total illicit traffic in amphetamine drugs.

The production of amphetamine last year

was about 75,000 pounds, enough to make about 3.5 billion amphetamine tablets, or about 20 tablets for every man, woman, and child in the United States.

Amphetamine is a central nervous system stimulant which taken under proper medical supervision has proved helpful, I am told, in selected cases of obesity, mental depression, and a number of other conditions.

It is when it is sold and used indiscriminately that the danger arises. When it becomes a bootleg product, this useful and powerful drug can readily become the accomplice not only of highway tragedy but of organized crime, juvenile delinquency, and quite possibly drug addiction.

According to medical experts in the Food and Drug Administration, amphetamine is much too potent a drug to be taken without medical supervision. For example, it may produce excessive nervous stimulation, loss of desire for sleep, impairment of judgment, hallucinations, and mental derangement. The amount of the drug required to produce these side effects varies widely from person to person. Under the Federal Food, Drug, and Cosmetic Act, it is illegal to dispense this drug without a doctor's prescription.

The prevention of desire for sleep is the basis for a large illegal trade in amphetamine among long-haul truckdrivers to enable them to stay awake beyond the limits of physical and mental endurance. While it is difficult to prove conclusively that any particular highway accident was due to the use of amphetamine by the driver, the drug has been found on drivers in a number of fatal highway traffic accidents, and there is other circumstantial evidence to implicate the drug in these accidents.

It is a well-established medical fact that prolonged wakefulness, beyond the fatigue limit, will result in a loss of muscular and mental coordination, impairment of judgment, and hallucinations. For example, a driver under the influence of the drug may see a mirage of an oncoming truck which may cause him to swerve off the road or into another vehicle which he didn't see.

Manufacturers, wholesalers, and retail drug-stores have a clear moral as well as legal responsibility to see to it that all dangerous drugs are kept in authorized channels leading ultimately to sale by a qualified pharmacist only on prescription.

In this connection, I should like to call particular attention to a decision rendered on September 30, 1959, by the U.S. Court of Appeals for the Fifth Circuit, in the case of Dr. Samuel J. DeFreese and Marsha Jean Simmons DeFreese versus United States. This case was on appeal from the U.S. District Court for the Middle District of Georgia. The defendants and appellants argued, among other things, that the wholesaling of amphetamine to a truck-driver was not "dispensing" within the meaning of the Federal Food, Drug, and Cosmetic Act. The court, I am happy to say, rejected this contention.

The Food and Drug Administration, with the excellent cooperation of the Departments of Justice and State and local police departments, is doing what it can to put a stop to the illegal

traffic in amphetamine drugs. This campaign will not only be continued but intensified in every way possible.

However, in view of the magnitude of the traffic in these drugs, I believe the present law does not provide the most effective way to get at the problem. We are therefore considering ways in which the legislative authority for dealing with this situation can be improved, and I expect that we will have a constructive proposal in this area to submit to the next session of Congress.

There are several ways in which existing law could be strengthened to improve the enforcement program. We are seriously considering such additional legislative requirements as the following:

1. That manufacturers, wholesalers, and retailers be registered to enable identification and that they be subject to Federal inspection.

2. That manufacturers, wholesalers, and retailers keep records of sales of the drug, with a penalty provision covering the falsification of such records.

3. A provision defining unauthorized possession of the drug as an offense.

4. A congressional action which finds that any illegal sale of the drug (whether or not the drug was in interstate commerce) is in effect a "burden" on legitimate interstate commerce, and hence subject to Federal control, thus making it unnecessary to prove interstate shipment in each bootleg sale.

Courses on Radionuclides in Food

A course in radionuclides in food will be offered again during April 18-29, 1960, at the Robert A. Taft Sanitary Engineering Center, Public Health Service, Cincinnati, Ohio. Presented first in September 1959, the course is designed for persons responsible for monitoring radioactive materials in milk and food.

Subjects include methods for sampling and assay of radioactive contaminants, data interpretation, radiation fundamentals and instrumentation, and sources of radionuclides in foods.

Applications should be addressed to the Chief, Training Program, Robert A. Taft Sanitary Engineering Center, 4676 Columbia Parkway, Cincinnati 26, Ohio, or to the director of a Public Health Service regional office.

Hospital Use in Massachusetts, 1945-1955

A. DANIEL RUBENSTEIN, M.D., M.P.H., HENRY R. MASON, M.P.H.,
and ELIZABETH L. STASHIO

DETAILED information concerning hospital use is urgently needed at a time when construction and operation costs of hospitals continue to rise. How has the shift of population in metropolitan areas from the core cities to suburbia influenced hospital utilization in medical teaching centers and institutions located in central areas? Why do some communities have higher rates of hospitalization than others? And, finally, are we prepared to develop criteria for determining reasonable or adequate levels of utilization?

To begin to answer these and related questions, a survey of hospital use in Massachusetts in 1955 was compared with a similar study undertaken 10 years previously when hospital service areas were first drawn up for the Federal hospital survey and construction program. Data on hospital admissions for the State's entire population residing in 351 cities and towns were gathered from the 163 general hospitals caring for acutely ill patients in 1945 and from the 149 such hospitals in 1955. All inpatient admissions with the exception of the newborn were counted. Data for the newborn were collected separately and were used to represent maternity admissions in these studies.

The grouping of cities and towns into 68 hospital service areas located in 6 regions of the State greatly facilitated the tabulation and analysis of hospital utilization data. Admissions to State and Federal military and veter-

ans hospitals and to long-term or chronic institutions were not included in these studies. Admissions for out-of-State residents were segregated from those for persons residing in Massachusetts. The community residence of all but 220 patients was available in the 1945 study, and of all but 833 patients, or less than one-tenth of 1 percent of all admissions, in the 1955 survey. Data concerning the community residence of maternity patients (as determined by the count of newborn) were also gathered for each of the 2 years.

Pattern of Admissions

In the 10-year period 1945-55, total hospital admissions for Massachusetts residents per 1,000 population increased from 109 to 124. Although there were 14 fewer general hospitals in the later year, the total number of admissions (including maternity cases) increased 22.2 percent, and maternity admissions increased 3.1 percent. The State's population in this decade increased 7.7 percent. In 1945, maternity patients constituted 20.0 percent of all general hospital admissions; in 1955, they represented 17.01 percent of the total admissions.

The greatest percentage increase in admissions occurred in hospitals located in the rural and urban fringe communities. This was true of maternity cases as well as total admissions (see chart). In fact, the increase in maternity admissions in these areas was strikingly greater than the increase in either of the other two types of communities. General hospitals in the large urban communities—Boston, Cambridge, Worcester, and Springfield—experienced the smallest increase in total hospital

Dr. Rubenstein is director of the bureau of hospital facilities, Massachusetts Department of Public Health. Mr. Mason, now with the American Medical Association, was survey administrator, and Miss Stashio is senior statistical clerk with the bureau of hospital facilities.

admissions. Their increase in maternity admissions exceeded that in the small urban communities, but was nevertheless much smaller than in the rural and fringe areas.

These findings reflect to a great extent the shifting of population from the large cities to the less densely populated areas of the State. Another factor has undoubtedly been the increase in number of suitable beds available in the rural and urban fringe areas. Almost half of the general hospital beds in these areas considered nonacceptable in 1945 because they were located in obsolete or inadequate buildings had been replaced with acceptable beds by 1955 (7).

In comparison with the other two types of communities, the small urban areas did not experience an increase in general hospital admissions proportionate to their population growth. Also, their increase in maternity admissions was insignificant (0.2 percent).

These findings suggest that an increasing number of residents of the small urban areas are using the hospitals in the large urban medical centers.

Study of hospital admissions according to residence of patients revealed that the rate of hospital use was generally greater for residents of the large urban areas than for persons residing in the small cities or in the rural and fringe areas both in 1945 and 1946. For residents of the large urban areas, admissions rose from 119 per 1,000 residents in 1945 to 134 in 1955. In the small urban areas, the admission rate increased from 104 to 119, while in the fringe and rural areas the admission rate rose from 107 to 121.

Special attention was drawn to two large urban communities and one small urban community which showed unusual changes in rates of hospital admissions over the 10-year period.

Percentage increase in population, total admissions to general hospitals, and maternity admissions, from 1945 to 1955, Massachusetts

Table 1. Relation of general hospital admissions to beds available in selected Massachusetts communities

Communities	Hospital admissions per 1,000 population		Hospital beds per 1,000 population	
	1945	1955	1945	1955
Worcester-----	116	139	4.0	4.6
Springfield-----	121	118	3.7	3.2
Pittsfield-----	111	145	4.3	5.0
State as a whole--	109	124	3.8	3.9

In the Worcester metropolitan area, hospital admissions went from 116 to 139 per 1,000 population, while in the Springfield metropolitan area, only 50 miles from Worcester, the rate dropped from 121 in 1945 to 118 per 1,000 population in 1955 (table 1). In the smaller city of Pittsfield, general hospital admissions increased from 111 to 145. Examination of the ratios of hospital beds to population in these three communities revealed a possible influential factor in these changes. In 1945 Worcester had 4 general hospital beds per 1,000 population, and Springfield had 3.7 beds per 1,000. However, in 1955, Worcester's bed ratio rose to 4.6, while Springfield's dropped to 3.2 per 1,000. In Pittsfield, the hospital bed ratio rose slightly more than in Worcester, from 4.3 to 5.0 per 1,000 population. Such a positive correlation between utilization of general hospitals and the number of beds available has been observed recently by Shain and Roemer (2).

Study of the extent to which residents used hospitals in their own areas or in other areas revealed little change between 1945 and 1955 (table 2). There was, however, a small increase (1.6 percent) in use of rural hospitals by residents of rural and fringe areas and a similarly small increase (1.4 percent) in use of large urban hospitals by residents of small urban communities. There was also little change in the hospitals used by out-of-State residents, who accounted for 4.5 percent of all admissions to general hospitals in Massachusetts in 1945 and 4.2 percent in 1955.

Data on hospital use in Boston suggest that residents of the city who migrated elsewhere

in the State continued to use the city's general hospitals. In 1945 the population of Boston was 766,386, or 17.1 percent of the State's total. In 1955, the population was 41,684 smaller and constituted only 14.9 percent of the State's population. In the earlier year, 56.8 percent of the patients using Boston hospitals were residents of the city, whereas in the later year admissions of Boston residents diminished to 50.2 percent of the total patients admitted. Conversely, patients residing elsewhere in Massachusetts constituted 40.9 percent of the patient load in 1955, as compared with 34.5 percent in 1945. (The remainder of the patients in each year were out-of-State residents.)

Summary and Discussion

Our studies thus far indicate that there has been a marked increase in use of general hospitals in Massachusetts between 1945 and 1955. In the State's four largest cities, hospital use increased substantially despite the fact that their aggregate population remained practically constant. The small cities and the rural and fringe communities experienced more marked increases along with relatively large population growth.

Hence, generally speaking, as the population has shifted from the cities to the less densely populated areas, hospital use has changed in the same direction. This relationship is true also of maternity admissions, at least in the rural and fringe areas. There are indications,

Table 2. Percentage distribution of patients according to residence, by place of hospitalization, Massachusetts, 1945 and 1955

Residence	Place of hospitalization					
	Large cities		Small cities		Rural and fringe areas	
	1945	1955	1945	1955	1945	1955
Large cities-----	91.5	91.7	7.2	6.7	1.3	1.6
Small cities-----	17.1	18.5	80.8	79.5	2.1	2.0
Rural and fringe areas--	19.5	19.5	17.9	17.9	61.0	62.6
Out-of-State-----	67.9	68.9	28.6	28.3	3.5	2.8

however, that an increasing number of inhabitants of small cities, some undoubtedly former residents of the large cities, are continuing to use facilities of the large teaching and medical center hospitals. While the small cities experienced a 10 percent population growth in the 10-year period, their hospitals showed only a 0.2 percent increase in maternity admissions.

These studies give substantial support to the thesis that the volume of admissions to hospitals in a community is directly related to the number of beds available in that community. It is apparent that hospitals located in the rural and urban fringe areas have been so well accepted by the public that the use of "population size" as the main criterion for measuring need for hospital beds has been validated.

Other variables, not considered in these

studies, have been suggested as factors also affecting hospital use. These include numbers and kinds of prepayment plans available, practice patterns of local physicians, and availability of outpatient services. Only after all such factors have been analyzed in relation to use of hospitals will it be possible to develop suitable criteria for determining adequate levels of hospital use and hospital bed needs in local communities.

Rheumatic Fever Leaflet

HEALTH EDUCATION CASE HISTORY

Nine stages in the development of a leaflet on rheumatic fever recently published by a large industrial concern are described for *Public Health Reports* by a science writer who prepared it.

As a first step, it was agreed in consultation with the medical director's organization that an issue of the company's periodic health leaflet would be given to the topic of rheumatic fever.

Second, he read up on the subject in the latest medical books, in current medical periodicals, and in documents supplied by the American Heart Association.

Third, he attended as many meetings as he could where rheumatic fever was discussed.

Fourth, he showed a first draft and a layout of the proposed leaflet for comment to the American Heart Association, the local heart association, a medical consultant, and his wife.

Fifth, he incorporated the comments and criticisms received from these sources into a revised layout and text, which he submitted to the company for review and approval.

HEALTH EDUCATION CASE HISTORY

Sixth, changes suggested by the medical director's organization were made and the layout was approved by the company medical director.

Seventh, the text and layout were given to an artist, also engaged by the company, with suggestions for illustrations and colors as well as size specifications.

Eighth, the artist's layout and sketches were reviewed and okayed.

Ninth, all artwork copy was delivered to the company for printing and distribution.

This and similarly prepared leaflets on other health subjects of interest are distributed periodically to this company's employees throughout the United States. A survey has shown these leaflets to have popular appeal and acceptance by the employees. Requests for these leaflets come from students, teachers, nursing schools, health organizations, and others. A single request has called for as many as 300,000 copies. Since these leaflets are issued for employees rather than as a public service, they are supplied to the public only in limited quantities and then only when extra copies are available.

HEALTH EDUCATION CASE HISTORY

Screening Relatives of Diabetics in Five Florida Counties

L. L. PARKS, M.D., M.P.H., QUENTIN R. REMEIN, LYDIA S. SHIELDS,
and JAMES TURVAVILLE

THAT DIABETES "runs" in families has been recognized for many generations, but this knowledge is seldom applied to community diabetes detection programs if one judges by the literature. Screening relatives of persons with diabetes is a continuing activity in Florida. This report describes the detection project in Hillsborough, Jefferson, Madison, Suwannee, and Taylor Counties during the period January through June 1958.

Programs for diabetics in Florida began in 1935 when a member of the State legislature for Polk County, who was a diabetic, presented a bill to provide funds to purchase insulin for the indigent diabetics in the State. The legislature has appropriated funds for this purpose, included in the State board of health budget, for every year except one when the item was not included in the budgetary request. The appropriation for 1959 was approximately \$40,000.

In 1946 the Public Health Service conducted a diabetes screening demonstration among the general population of Duval County, including Jacksonville. The Service also provided educational services, conducted classes for diabetics, and made other studies. Subsequently the

State board of health used a trailer that toured various counties to conduct diabetes screening among the general population. The trailer service was discontinued about 8 years ago because of lack of funds.

One of the studies related to the 1946 demonstration undertook to determine the prevalence of undetected diabetes among blood relatives of known diabetics in Duval County. The basis for the study was the long-observed, familial pattern of diabetes confirmed by numerous genetic studies. In the Duval County study (1) during the 3-year period from 1947 to 1950, 1,741 relatives of diabetics were given laboratory tests for diabetes, and 73 new cases of diabetes (4.2 percent of those tested) were discovered. The percentage of cases detected among relatives of diabetics was found to be about five times as high as the percentage found in screening general population groups.

After several years during which casefinding activities based on screening relatives of known diabetics were not feasible, the Florida State Board of Health undertook in 1957 to capitalize on the unique opportunity afforded by the State's purchases of free insulin for indigent diabetics. In 1957 approximately 2,700 diabetics received part or all of their insulin through the State board of health.

Casefinding among relatives has several advantages which were helpful in reactivating the diabetes detection program in Florida. Screening can begin with small groups of persons and yet have a sufficiently high rate of yield to make a small program productive.

Dr. Parks is director of special health services, Florida State Board of Health, Jacksonville. Mr. Remein is associate chief, Operational Research, and Mrs. Shields, public health analyst of the Chronic Disease Branch, Division of Special Health Services, Public Health Service. Mr. Turvaville is a field-worker with the division of chronic disease, Florida State Board of Health.

Such a program is adjusted easily to the staff and funds available merely by contacting greater or smaller numbers of diabetics for the names of their relatives.

The pattern of administration of the insulin purchase program is ideal for involving local health departments in diabetes casefinding.

The State board of health purchases the insulin and keeps the records; local health departments distribute the insulin and contact the diabetics.

The 1958 diabetes detection project to screen relatives of diabetics was designed on a small scale. Its supervisor was a fieldworker from the chronic disease division of the State board of health. Local health department clinics did the screening, State and local staffs jointly participated in the followup of relatives, and the State laboratory ran the tests. The Public Health Service cooperated by supplying funds to assist the program operation and by analyzing the data for the period January through June 1958.

These criteria governed the selection of participating counties: (a) the number of indigent diabetics residing in the county; (b) location of the county; (c) the county health officer's desire to participate in the program; and (d) approval of the program by the county medical society. Because of local health department needs and interests, rather flexible procedures were established and the details of methods differed among the various counties.

In general, when the several criteria for par-

ticipation had been met in a specific county, a mailing list was prepared from the roll of diabetics receiving free insulin. A letter of explanation and a questionnaire was sent to each diabetic asking him to give the names and local addresses of his blood relatives, including parents, children, grandparents, siblings, aunts, uncles, and first cousins. Postage prepaid return envelopes were enclosed with the questionnaire. If possible, a visit was made to try to locate and interview diabetics who failed to return their questionnaires.

A letter was prepared and sent to each relative with a local address named by the diabetic. The letter explained the purpose and the importance of a diabetes detection test, invited the relative to have a test at the health department at a specific appointment time, and asked that he notify the health department if the time were inconvenient so that another appointment could be arranged. It suggested that the relative, if he preferred, go to his family physician for the test. The letter also listed several menus, each containing approximately 100 mg. of carbohydrates, and stated that one of these meals should be eaten 2 hours before the appointment for the test. When they had time, health department staff members visited and offered a blood test to relatives who had not reported to the health department or gone to their family physicians for a test.

In the screening, blood sugar determinations were made by the Somogyi-Nelson method. A level of 130 mg./100 ml. of venous blood or higher was considered positive. For some very young children, urine specimens were exam-

ined by the Tes-tape method. Relatives who screened positive were advised to see their physician for further study and diagnosis. If they felt they could not afford a private physician, they were advised to contact the health department for further information. Those returning to the health department were then handled according to local regulations. The referral physician or clinic made the diagnosis.

Results

During the 6-month period, 263 indigent diabetics in the five participating counties responded with information on their relatives. The distribution of the diabetics by age, race, and sex is shown in table 1. Their average age was 59 years. No effort was made to compare these respondents with diabetics from whom no information on relatives was elicited.

The diabetics identified 935 relatives, an average of 4 relatives per patient, and 452 relatives were tested. The percentage of relatives tested did not vary greatly by age except for a high response rate among children (table 2). In most screening programs in the general population the response rate in the older ages declines. It is possible that the direct, personal approach afforded by this casefinding method was responsible for the fact that the response rate did not fall off in the older age groups. Of course, the group was not large and other unknown, chance factors may have been operating in favor of this kind of response. Achieving

among the aged a response approximating the average rate for the entire group is particularly significant for casefinding purposes in view of the high prevalence of diabetes in this age group.

Table 3 shows the percentage of relatives tested by relationship to the diabetics supplying information. The female relatives had a higher response rate in each instance than the corresponding male relatives. The highest response rate was found in grandchildren, followed by parents, children, and siblings, in that order. The first column also shows the distribution of the relatives named according to relationship. As might be expected from the age distribution of the diabetic patients, the relatives most frequently named were children, siblings, and grandchildren. There were relatively few parents and only two grandparents (not shown separately).

Table 4 indicates that the rate for previously known diabetics among the relatives is 8.8 per 1,000 persons tested, which is equal to the recent national prevalence estimate for previously known diabetes (2). This is also similar to the rate of 9.6 per 1,000 obtained in other Florida casefinding programs in recent years. The yield in previously unknown diabetes was 22.1 per 1,000 persons tested. This is more than 2½ times the national estimated prevalence rate of

8.1 unsuspected cases of diabetes per 1,000 population and more than three times the yield of previously undiscovered cases in the average program reported to the Chronic Disease Branch, Public Health Service. In 64 screening projects with diagnostic information reported, the average program found 6 previously unknown diabetics per 1,000 tested.

Results by age among the relatives of diabetics follow a pattern similar to that in general population screening. The rate of diabetes discovered increases with age. Making use of this phenomenon could greatly increase the yield per person tested. If children under 15 years of age had been excluded, the yield would have been 30.3 previously unknown cases per 1,000 tested. If relatives under 35 years of age had been excluded, a yield of 41.9 per 1,000 tested would have resulted. This latter rate is over three times the rate of previously unknown cases found in screening adults in the general population in Florida. During the period September 1955 through January 1957, seven diabetes screening programs were conducted in the State among persons 30 years of age or over. In screening over 16,000 persons, a rate of 12.9 previously unknown diabetes cases per 1,000 tested was obtained.

All diabetes cases were found among the parents, children, and siblings of diabetic patients

¹ No cases found.

diabetes cases in this study are not as great as those obtained in the Duval County study (1). The rates by age group in both studies are compared in table 7. No cases of diabetes among relatives under 15 years of age were found in either study. The greatest difference was in the age bracket 35-54 years in which the five-county project had a much lower yield. The factors accounting for these differences are not known.

Discussion

Screening relatives of diabetics has proved to be a practical method of finding cases of diabetes in Florida. Through a unique program of insulin distribution, indigent diabetics can be reached readily. Elsewhere, various ways can be used to develop similar programs. The relatively large diabetes clinics of most general hospitals and outpatient departments provide excellent sources from which to obtain a diabetic population. In some areas it may be possible to secure names of diabetics from local physicians cooperating in casefinding. Diabetics could be reached with informational materials through their physicians or pharmacists and invited to participate by referring relatives for testing. In general community casefinding programs all persons found to have diabetes should be interviewed to obtain information on relatives who could be offered a blood screening test.

In planning diabetes programs, we would reiterate suggestions often made but infrequently heeded, suggestions whose worth has been borne out again by experience in this project. Concerted education and information efforts greatly reduce misunderstandings and problems and improve participation all along the line. Personal interview or personal followup after distributing the initial questionnaire increases

participation by diabetic patients. Likewise, personal fieldwork improves the response rate of the relatives and their followthrough to diagnosis when indicated. Since a number of relatives were not screened because of working hours, some evening clinics seem to be highly desirable to improve response. Costs have not been studied in this project, but it is clear that a somewhat greater investment to insure a high response rate is warranted when the yield in previously undetected cases is high.

As previously indicated, the yield rate can be significantly increased by not testing persons under 15 years of age. Of course, this rule need not be followed strictly if it reduces rapport with diabetic patients and their relatives. It also may be desirable to test only grandparents, parents, siblings, children, and grandchildren if it is necessary to limit the program.

Summary

A total of 263 indigent diabetics in five counties of Florida named 935 relatives, of whom 452, or 48.3 percent, were tested for diabetes. The rate of previously known diabetes was 8.8 per 1,000 tested and the yield of previously unknown cases of diabetes was 22.1 per 1,000 tested. This yield is more than three times the usual yield in diabetes screening programs in general population groups. While the number of diabetics found was small, the results support previous findings that this is a practical casefinding method with a high rate of yield.

irrespective of the nomenclature of the degree. A list of all schools offering such training is available from the authors. Similar data for the period since 1889 appear in the literature (1-4) or have been distributed by the Public Health Service.

Comparative data on the conferment of

Prepared by Frederick K. Erickson, S.M., and Frank A. Butrico, M.S.S.E., Office of Engineering Resources, Division of Engineering Services, Public Health Service. Mr. Erickson is sanitary engineer director, and Mr. Butrico, chief of the office.

degrees for the years 1951-58 are given in the tabulation above.

Undergraduate Degrees

Forty-five institutions offered undergraduate electives in sanitary engineering during the academic year 1957-58. Thirty-three of these schools reported that 148 graduates had received undergraduate training toward the bachelor's degree in sanitary engineering or had a sanitary engineering major or option. Undergraduate emphasis on sanitary engineer-

ing continues to show a downward trend. The average number of graduates per year for the 10-year period 1948-57 was 202, and for the 5-year period 1953-57, 175.

Master's Degrees

Thirty-five of the 68 schools offering graduate training for the master's degree in sanitary engineering awarded 128 degrees, 29 of them to foreign nationals. The remaining 31 schools (45 percent) reported no graduates.

Eleven schools had 4 or more graduates and accounted for 87 of the total number of degrees conferred at this level. Of these 11 schools, 6 have averaged over 5 master's degrees per year for the 10 years 1949-58. The average number of master's degrees conferred per year for the 10-year period 1948-57 was 134, and for the 5-year period 1953-57, 126.

Doctor's Degrees

In 1958, 12 institutions awarded a total of 16 doctor's degrees in sanitary engineering, 4 of

them to foreign nationals. Twenty-five other schools offered a sanitary engineering program at the doctorate level, but reported no awards of degrees.

Three of the 12 schools have awarded 1 or more doctor's degrees each year for the past 5 years and have accounted for over 55 percent of the doctorates in sanitary engineering over that same period. For the 10-year period 1948-57, the average number of doctor's degrees per year was 7.3, and the average for the 5-year period 1953-57 was 9 degrees.

Exhibit on PHS Contributions to Medical Research

An exhibit on some of the contributions of the Public Health Service to medical research during the period 1900-1940 was held in the Service's National Library of Medicine from September through November 1959.

Selected papers, books, some in foreign languages, reports, memorabilia, and photographs demonstrated the work of a number of Public Health Service scientists who were associated largely with the Hygienic Laboratory and the National Institutes of Health. Their activities advanced knowledge of such diseases as hookworm disease, tularemia, pellagra, plague, Rocky Mountain spotted fever, encephalitis, psittacosis, and typhoid and typhus fevers. Contributions were also in chemistry and pharmacology—hydrogen ion determination, discovery of the thyroid hormone in the blood, and antineuritic vitamins.

Scientists represented in the exhibit were Dr. Milton Rosenau, Dr. John F. Anderson, Dr. George W. McCoy, Dr. R. E. Dyer, Dr. Edward Francis, Dr. James P. Leake, Dr. Charles Armstrong, Dr. Wade H. Frost, and Dr. William Wherry. Chemists, pharmacists, and zoologists were Reid Hunt, Atherton Seidell, Maurice I. Smith, William Mansfield Clark, and C. W. Stiles.

STATEMENT

By Arthur H. Wolff, D.V.M., Division of Radiological Health, Public Health Service, before the Special Subcommittee on Radiation of the Joint Congressional Committee on Atomic Energy, May 6, 1959

Fallout and Uptake of Iodine-131

In considering the uptake mechanism for fallout, almost exclusive attention has been given to strontium-90. Strontium-90 as an environmental contaminant certainly deserves primary attention because the problem will persist for years following the cessation of nuclear weapons testing. Even though strontium-90 is the nuclide of major significance, the potential hazard of some of the shorter-lived nuclides should not be overlooked. Some of the other fission-product radionuclides are not necessarily insignificant just because they are short lived; they may present a contamination problem if they are sustained in the biosphere at relatively high levels.

Of particular importance in this regard is iodine-131, a fission-product radionuclide with a half-life of approximately 8 days. Iodine-131 is unique among the fission-produced radionuclides in that it concentrates in a small gland, the thyroid. Consequently, extremely small amounts of the nuclide taken into the animal body will result in relatively high dosages to a single gland as compared with equal amounts of other radionuclides more widely distributed in the body.

As a result of its 8-day half-life the concentration of iodine-131 in a gross fission-product mixture gradually diminishes, and the amount of iodine-131 reaches negligible proportions several weeks to months following its creation. It is likely, therefore, that any iodine-131 in the biosphere results primarily from rather fresh fallout.

Several investigators have measured the iodine-131 levels in the thyroid glands of grazing animals as an index of fresh fallout in various parts of the world. Much of the work in this

field has been done by Dr. Lester van Middlesworth, University of Tennessee, Memphis. Since 1954 he has collected thyroid glands from animals in slaughterhouses from various countries and particularly from Tennessee in this country. From 1955 to 1958, based on his data the average concentrations of iodine-131 sustained in U.S. cattle and sheep were in the order of 700 and 3,000 micromicrocuries per gram of thyroid respectively. The average weekly dose was about 60 millirad per week for cattle and 250 millirad per week for sheep. These concentrations are average values; considerable fluctuations occurred according to the type and location of weapons testing in progress just prior to the time of collection. Other investigators (1-4) have found similar levels in other parts of the United States.

It is apparent that despite its short half-life iodine-131 has been readily detectable as a biospheric contaminant reflecting current weapons tests. The levels found are quite likely innocuous insofar as the health of the animals is concerned. However, iodine-131 as a biospheric contaminant probably has resulted in a higher dosage level to any given volume of tissue than has any other fission-product nuclide.

The levels of iodine-131 in grazing animals are considerably higher than any levels concurrently found in humans because grazing animals consume large quantities of foliage upon which fallout and rainout are directly deposited.

The values in cattle are of particular interest because, theoretically, we should also expect detectable quantities of iodine-131 to be secreted into the milk. The Public Health Service has therefore included iodine-131 as well as certain other short-lived radionuclides in its milk sur-

veillance program. The average iodine-131 levels detected in milk from various sampling stations are shown in the table.

Dr. E. B. Lewis, California Institute of Technology, has submitted a statement for the record which estimates the human dosages and possible biological significance that would be associated with consumption of milk containing the levels of iodine-131 reported here.

Iodine-131 levels in cattle thyroid may provide a presumptive index of the levels secreted

into milk in the same area. This is one parameter which the Public Health Service hopes to investigate in its future work in radiation surveillance of the environment.

The technique for measuring iodine-131 levels in thyroid glands is relatively simple. Perhaps greater reliance should be given to this technique, for it may serve not only as an early and sensitive index of the biological incorporation of iodine-131 but also may provide an index of the biological accumulation of other fission products. Iodine-131 as an index of environmental contamination, however, is only applicable to fission products of recent origin.

Residence Requirements and Federal Aid

Both the Federal Government and our State governments must come to grips with some basic issues in connection with the administration of our Federal-State programs of public assistance. . . .

To the extent that funds are utilized for public assistance purposes, there should be no residence requirement by the States. The Federal Government is making funds available in order that persons who are in need may receive assistance. It has no concern and should not have any concern about how long persons have lived in a particular community or State. In fact, I feel that it is indefensible for the Federal Government to continue to permit the restriction of the use of its funds in this manner.—ARTHUR S. FLEMING, *Secretary of Health, Education, and Welfare, at the Governors' Conference, San Juan, Puerto Rico, August 4, 1959.*

Reinforcement of Family Ties

GERALDINE GOURLEY

DURING the past several years, there has been increasing concern about an apparent weakening of the family as a strong, effectively functioning entity. This concern is shared by other countries across the world, where industrialization and other "benefits" of Western culture are accompanied by a breakdown in family life.

There have been many attempts to explain the reasons for this situation which we will not try to explore, but it does behoove each of us who has a responsibility for working with families to ask whether our efforts contribute to or threaten any aspect of family security and strength.

The importance of the family, both as a social force and as the basis for healthy personality development, is consistently stressed. We have swung from rigid routines in baby care to self-demand feeding, from early toilet training to self-discipline, and have made many changes in our ideas of what is "good for people." But at least intellectual acceptance of the value of the family has remained constant. Emphasis is, in general, on the primary family with some recognition that it does not exist in a vacuum, but is a member of a community. There is less expressed recognition that this family is also a member of a family, and of a social group from which it derives its identity.

Relationships inherent in the extended family have almost disappeared from segments of

our population. In certain groups these broad family ties still exist and are important. And, for those of us who may have lost these close ties, there is often a sense that here we may have lost something of value. How often have we heard our mobile friends say wistfully that "the family is so separated," a note of regret that there is, for their children, so little sense of family that reaches beyond the typical American home? One of the plausible explanations of the cause of weakened family effectiveness is the lack of roots in broader family relationships. What additional strains are placed on parents where support from and close identification with their own families are missing? What is lacking for a child who does not feel a close part of a family which reaches beyond his own household? If we can concede that these are important relationships to conserve and strengthen, we must consider the part we play in strengthening or threatening these ties and, thereby, in affecting the ability of the family to meet its obligations successfully.

The Figure of Authority

Studies have been made to evaluate the secondary effects of health programs which substitute professional authority for the traditional teaching by older family members, experienced neighbors, or other key persons in the social group. It seems safe to speculate that these changes in authority figures are not without significance. And we might further speculate that, when these persons are divested of authority and respect in such vital fields as family health and child rearing, this may carry over into other areas of relationship. Can members of the family or social group, whose ideas on

Miss Gourley is a medical social consultant in the child development center of the New Mexico Department of Public Health in Santa Fe. The paper was presented at the 17th annual meeting of the United States-Mexico Border Public Health Association in Brownsville, Tex., April 1959.

these matters have been labeled "wrong," "misinformed," even "bad," be expected to retain respectful consideration for their attempts to support social values basic to family functioning within the specific culture?

No one of us who has worked in public health questions that there are health practices which we must attempt to change. This is a large part of our reason for being. But we may need to weigh the actual health implications of some ill-favored practices against the possibility of strained relationships within the family or social group.

In the past few years we have become imbued with the importance of "culture." We find extensive material in health journals stressing the need for knowledge about and respect for the cultural background, beliefs, and customs of any group affected by health programs.

Culture is, of course, not the exclusive property of these groups sometimes described as "backward" and "interesting." As health workers we have a definitely ascribed culture which influences our own attitudes and behavior. Practices of child care, family management, medical care, and general patterns of family living which differ from the accepted theories and practices of the culture to which we belong, or aspire, may be labeled as "wrong," "misinformed," or, even worse, as "quaint" and "amusing" and therefore not to be considered seriously.

With our "scientifically oriented" beliefs about what contributes to or threatens health, there is a strong temptation for professional workers to have a sense of the rightness of our authority. After all, don't we represent a way of life which produces statistics showing significant decreases in morbidity and mortality, better teeth, and children who can tip the scales at a higher level? This very assurance of authority has contributed to parents having a tendency to become dependent on professional workers. If the professional worker feels that his role entitles him to this authority and derives satisfaction from having people depend on him for advice and help, he may voluntarily or involuntarily develop willing and compliant followers. But the professional worker cannot and would not be willing to fulfill the role of those persons who may be estranged by this

transfer of dependency, nor can he satisfy the emotional needs which can only be met within the family or social group.

Any attempt to bring about changes which may result in friction, resentment, or lessened sense of value to any important family member, or threaten the parents' position in the social group with which he is identified, should be made only with full knowledge of possible consequences. When, after such a careful evaluation, we feel convinced that change is important for the welfare of the family, we must make as earnest an effort to handle possible family tensions as we make to alter the health practice itself. Pressure for change tends to produce strain, since it implies criticism of previous methods. We can partially balance this strain by consciously reinforcing those things in the culture which are important and which provide stability.

To deprive the older family member of her authority on what constitutes proper feeding of the family and the appropriate way to treat a child's illness, and still show respect for her role, is not easy. It can be done convincingly only if we have real conviction of her importance. The effect of a tolerant but condescending smile, the summary dismissal of a family health practice or social custom, may have more disrupting effect on family relationships than we realize; on the other hand, the genuine respect of a professional worker for the authority figures in a social group may give them much-needed support in fulfilling their roles and contributing to family strengths.

In a number of instances, programs reflect an attempt to avoid or mitigate the threat to family and group solidarity from situations produced by change. Classes for expectant mothers, for example, have included expectant fathers and grandmothers, as well as other group members who represent authority. This would seem to be worth while since there is no time in a young woman's life when she is more in need of family acceptance and support. It is also a most important event for the total family.

An important consideration in the success of such an experiment is the purpose and method of including these additional persons. How are these family "authorities" viewed by the pro-

professional worker? Are they expected to sit as listeners while we attempt to impart our health culture? Or are they encouraged to participate as recognized and respected authorities, with every possible support given their ideas even though some of them may have little scientific basis according to our present knowledge?

I use the term "present knowledge" advisedly. Some of us remember the days when we, with complete professional sincerity, contributed to making grandmother a dangerous character to be watched or she might rock the baby or slip him a between-feeding snack. Many a child was saved from the rigid schedule only because grandma knew too much to go along with the "education" of that day. And at how many foods and home remedies have we looked down our professional noses, only to go back to encouraging their use at a later date? Even when we can feel reasonably certain that a custom has no scientific health value, this does not mean that it holds no social value for the members of the group. Unless the practice is actually harmful, it can at least be given respectful consideration. Many a skillful nurse encourages the expectant mother to follow her own mother's advice regarding the *muneco*, or cloth band, around her waist to keep the fetus in place, at the same time that she attempts to influence her diet and general prenatal care. And at some of the hospitals caring for our southwest Indians, highly skilled physicians have realized the value of inviting medicine men to participate in the treatment of certain patients.

With all our best efforts to gain social group support for a family, there will be times when we have to encourage a parent to take a stand which we know may produce conflict. In these instances, we can at least attempt to develop sympathetic understanding of the feelings which may be aroused and lend our help so that the situation can be handled with minimum guilt and resentment. We must be as much concerned with helping parents maintain the best relationships possible as in supporting them to remain firm about a controversial family issue. Identification with a young mother against her unreasonable relatives or neighbors will serve no purpose. An attitude of "I am on your side; pay no attention to those misin-

formed and misguided advisers" will not be of lasting help. She will need these relationships long after we have moved out of the picture.

When changes may bring conflict between husband and wife, we need to take an even longer look at the advisability of supporting such recommendations. It may be of questionable value to have a child with good teeth and strong muscles, who is fed, toileted, and disciplined according to the latest theories, if friction between parents prevents family unity necessary for healthy emotional development.

Family Cohesion

Probably the most critical events in the life of any family, those experiences which have throughout time drawn families closest together, are childbirth and illness. The development of modern facilities is removing both of these from the home and away from the family.

Many of us have probably been in some way connected with a home delivery. This was certainly a family affair, with relatives and neighbors participating, and father and children waiting for a signal to claim the mother and new baby. The contrast with delivery in some of our hospitals has caused many thoughtful persons to question what may be the effect on family life and on the ultimate welfare of mother and child. In some of our hospitals we have come through the period when, for reasons of obsession with sterility or hospital routine, the mother disappeared into the mysterious recesses of the hospital, not to reappear again until it was "all over." The baby was immediately relegated to a separate nursery, scarcely to be seen thereafter except through a glass wall. The only visitor permitted on the ward was the father, and he was often so awed by the professional atmosphere that he sat out his visiting hour, stiff and uncomfortable, not daring to touch the baby which had been made so formidable by sterile precautions.

I will not be so heretical as to suggest that the figures presented to show increases in hospital deliveries may not always indicate unmitigated blessings. But certainly we can question hospital policies which preclude family participation. Some of our leading physicians and hospital administrators are successfully taking steps to

these matters have been labeled "wrong," "misinformed," even "bad," be expected to retain respectful consideration for their attempts to support social values basic to family functioning within the specific culture?

No one of us who has worked in public health questions that there are health practices which we must attempt to change. This is a large part of our reason for being. But we may need to weigh the actual health implications of some ill-favored practices against the possibility of strained relationships within the family or social group.

In the past few years we have become imbued with the importance of "culture." We find extensive material in health journals stressing the need for knowledge about and respect for the cultural background, beliefs, and customs of any group affected by health programs.

Culture is, of course, not the exclusive property of these groups sometimes described as "backward" and "interesting." As health workers we have a definitely ascribed culture which influences our own attitudes and behavior. Practices of child care, family management, medical care, and general patterns of family living which differ from the accepted theories and practices of the culture to which we belong, or aspire, may be labeled as "wrong," "misinformed," or, even worse, as "quaint" and "amusing" and therefore not to be considered seriously.

With our "scientifically oriented" beliefs about what contributes to or threatens health, there is a strong temptation for professional workers to have a sense of the rightness of our authority. After all, don't we represent a way of life which produces statistics showing significant decreases in morbidity and mortality, better teeth, and children who can tip the scales at a higher level? This very assurance of authority has contributed to parents having a tendency to become dependent on professional workers. If the professional worker feels that his role entitles him to this authority and derives satisfaction from having people depend on him for advice and help, he may voluntarily or involuntarily develop willing and compliant followers. But the professional worker cannot and would not be willing to fulfill the role of those persons who may be estranged by this

transfer of dependency, nor can he satisfy the emotional needs which can only be met within the family or social group.

Any attempt to bring about changes which may result in friction, resentment, or lessened sense of value to any important family member, or threaten the parents' position in the social group with which he is identified, should be made only with full knowledge of possible consequences. When, after such a careful evaluation, we feel convinced that change is important for the welfare of the family, we must make as earnest an effort to handle possible family tensions as we make to alter the health practice itself. Pressure for change tends to produce strain, since it implies criticism of previous methods. We can partially balance this strain by consciously reinforcing those things in the culture which are important and which provide stability.

To deprive the older family member of her authority on what constitutes proper feeding of the family and the appropriate way to treat a child's illness, and still show respect for her role, is not easy. It can be done convincingly only if we have real conviction of her importance. The effect of a tolerant but condescending smile, the summary dismissal of a family health practice or social custom, may have more disrupting effect on family relationships than we realize; on the other hand, the genuine respect of a professional worker for the authority figures in a social group may give them much-needed support in fulfilling their roles and contributing to family strengths.

In a number of instances, programs reflect an attempt to avoid or mitigate the threat to family and group solidarity from situations produced by change. Classes for expectant mothers, for example, have included expectant fathers and grandmothers, as well as other group members who represent authority. This would seem to be worth while since there is no time in a young woman's life when she is more in need of family acceptance and support. It is also a most important event for the total family.

An important consideration in the success of such an experiment is the purpose and method of including these additional persons. How are these family "authorities" viewed by the pro-

Anticipating Safety and Health Needs

HAROLD J. MAGNUSON, M.D.

FORESEEABLE changes affecting occupational health and safety needs may be considered as occurring in three areas: industrial technology, medical technology, and sociological change produced by a multiplicity of economic forces.

Technological Change in Industry

In the area of technological change, the event of greatest moment, perhaps, has been the onset of the electronic and nuclear energy age. New possibilities have opened up for the entire electromagnetic spectrum, ranging from the infrared waves to cosmic rays. We shall see an increasing use of manmade radiation not only as a source of power but also as a tool in the study of industrial processes and methods and in the control of product quality. Many predict that the peaceful use of nuclear energy will be a major influence in our civilization by 1980.

As one illustration, the microwave region has opened up broad new areas of research in many fields, with potential application to industry. Microwaves already are finding increased use in spectroscopy, radio astronomy, particle accelerators, radar, communications, and food sterilization. But, as is true of many other rapid developments, knowledge of the health effects of microwaves has not kept pace with their use.

Another technological development which has aroused considerable interest is automation.

Dr. Magnuson serves as chief of the Occupational Health Branch of the Public Health Service. The paper was read at the 1959 convention of the International Association of Governmental Labor Officials, which was held in Kennebunkport, Maine, September 9-12, 1959.

By no means new, automation has appeared in various guises, such as in automatic poison gas alarms and driverless lift trucks. Automation makes possible new products, processes, and production volumes, leading ultimately, as some expect, to larger work forces. Various industries, such as those engaged in the production of new synthetic fibers, antibiotics, and nuclear energy, critically depend on automatic controls for volume production and worker safety. That automation will find its way into more uses is indisputable. Only its degree of advance is uncertain because of the excessive cost of complete automation.

Because of its growing influence, automation deserves serious scrutiny from the standpoint of worker health. One of the most immediate problems coming to our attention is, in some instances, that of greater exposure to noise, resulting from the greater use of electrical motors and equipment in the factory. More nervous strain may also be expected from the character of automatic operations. The effect of errors is more serious, the responsibility of the maintenance worker is higher, and machines are more complex. Eye attention is also intensified by the concentration and close work and the focus on control dials, lights, and panels. As the need lessens for physical effort by workers tending automatic machines, a growth of the health problems associated with the sedentary worker may be expected. We may also expect psychological hazards to the worker from isolation, boredom, and even from increased leisure.

A third factor of health import on the technological scene is the fast-rising number of new chemicals. Figures reflecting the growth of the chemical industry stagger the imagination. Consider, for example, that there are 500,000 distinct chemical compounds in use in industrial

reinstate the arrival of a baby as a family affair. Rooming-in has proved most successful where properly administered. More flexible visiting policies which encourage families to visit the mother and baby have brought no alarming increases in infections nor have had damaging effects on mother and child. The era of rigid seclusion, however, has left its imprint. Certainly not all hospitals in this country have shown recognition that childbirth has more than physical significance. And our contribution to health practices all over the world will long be felt. Recently a physician from one of the medical schools in the United States told of an experience while visiting a hospital in South America. The local physician, who had spent some time at a medical school in this country, showed him the maternity ward. Mothers and babies contentedly shared the same room, with a basket for the baby attached to the bed. Relatives were visiting comfortably, making proper exclamations of pride over the new family member. The doctor apologized for the "primitive" conditions and explained that a new ward was soon to be constructed where babies could be segregated in a nursery according to the best standards in the United States. The U.S. doctor could only protest, "Don't let them! We are now trying to build a new ward to accomplish what you already have here."

The old picture of the family doctor sitting by the bed of the sick child, with parents standing tensely together at the foot, still hangs on many a wall. No one wants to return to that day. The parent of any seriously ill child gives deep thanks for the facilities of the modern hospital. But no parent wishes to be excluded from

his child's care at such a time. It has been adequately demonstrated that effective hospital care does not mean taking over a child and excluding the family from any significant part of the experience. Yet any one of us could tell of cases where the sick child has become the property of the hospital, with visiting hours and conditions prohibitive of family involvement, no planned efforts to maintain the patient as part of the family, and no apparent recognition of family fears, customs, or rightful interest. We could also cite problems arising when we have tried to get these children back in the families at the time the hospital is ready to give up its claim. I hope we can balance these experiences with those where the child was given medical care with an understanding that he was and must remain part of a family; that there were a number of family members and friends important to him, and where the whole experience was one that contributed to the child's development and to the ties which draw a family closer together.

I do not lay at the feet of the already overburdened and conscientious health worker the total responsibility for the rise and fall of family life. The most and the least that we can do, as professional persons concerned with total family health, is to consider all our efforts in the light of their significance for family functioning. We are in a position to make meaningful contributions to family life. When the day comes that all aspects of health, as defined by the World Health Organization, physical, social, and emotional, receive equal concern and emphasis, we may be able to play an even more important role.

as evidenced by these indexes, with the more traditional concepts of pathological change and possible compensable occupational damage.

With the advance of medical knowledge, we may also expect an increase in the number of diseases recognized as occupational. This increase would result from the greater recognition of an occupational factor in certain diseases formerly regarded as common to ordinary life, as well as the growing number of chemicals being introduced in industry.

In addition to improved recognition and detection of occupational diseases, we may look for further progress in their treatment. More recent therapeutic techniques, for instance, have used chelating agents in the treatment of certain illnesses. The chelating agents have the property of selectively removing certain metals from the circulation. For this reason, they have been found useful in treating metal intoxications, such as arsenic and lead poisoning. However, since such agents may also remove essential metals from the body, study has been needed of this possible hazard.

Sociological Developments

Against this background of change in industrial and medical technology, let us consider some of the sociological developments that influence health and safety needs. Unquestionably, the change in patterns of financing medical care is foremost. The vigorous growth of health insurance coverage reflects the conviction of the American public that the financial risks of illness need to be shared. To an increasing degree, such insurance coverage is being included in management-labor negotiations, so that both labor and management have a real concern about obtaining maximum medical care benefits at a minimum cost. At present, health insurance programs made available and paid for through the worker's place of employment cover more than 37 million employees and their 57 million dependents, a total of 94 million people (2).

The fact that management is increasingly obliged to bear all or part of the costs of illness, occupational or nonoccupational, has certain implications. The immediate effect has been to place increased emphasis on the prevention of

nonoccupational diseases, since these represent the greatest share of sickness costs and absenteeism. Another, and to us a more important, change may be anticipated. Up to now, it has generally been to management's advantage to deny occupational factors in the illness of workers so as to avoid compensation costs. However, as the costs of illness of all types become a management concern, we may expect a shift in this thinking. Management may logically come to view the early recognition of occupational factors as an opportunity to apply primary preventive measures and reduce the overall illness cost.

Another implication of management's concern with all types of employee illness is the possible tightening up of physical requirements for new job applicants. The degree to which this may be carried out is necessarily dependent on the labor supply. In the meantime, however, a very real problem involves the compensation aspects of employing workers with degenerative illness, such as heart disease.

A conservative estimate is that at least 5 percent of the working population has some form of heart disease. As a result of the cardiovascular diseases, an estimated 653,000 man-years are lost annually (3).

Numerous claims have been filed for heart attacks suffered during working hours, and there has often been a wide variation of medical opinion as to whether or not the heart attack was caused by the work. Because of the divergence of medical views, the heart case in industry has been a fertile field for litigation. All too often, cases have been tried on an emotional basis rather than on scientific fact.

In New York State alone, an average of more than \$4 million is paid every year for compensation of heart disease claims. This is 4 percent of the total amount awarded for all compensation claims each year (4).

Some action must obviously be taken if the millions of Americans with cardiac conditions are to be assured of continued employment. One possible solution may perhaps lie in the second injury fund, thereby protecting the final employer from the full brunt of the cost of a disabling illness.

Moving from this facet to the whole picture of workmen's compensation, we may expect to

production, all but a few hundred of them unknown on this earth 20 years ago. (7).

Among the newer, toxic chemicals we find the boranes or boron hydrides. Originally considered for high-energy fuels, these chemicals are now finding their way into industrial applications, as in new plastics. The foam plastics, which are gaining in usage, contain toxic aromatic isocyanates. Likewise, the versatile and numerous epoxy resins which have swept industry have created a problem. Practically no industry using them escapes an increased incidence of dermatitis. Sensitized workers must be removed from the job.

Other industrially important materials potentially hazardous include the organometallic compounds. The carbonyls of iron, cobalt, and nickel are now widely used as catalysts in the petroleum and petrochemical industries. Organic compounds of manganese are being studied as possible substitutes for or supplements to tetraethyl lead in gasoline. Most of these organometallic compounds are highly toxic substances.

These are but a few of a long, growing list of potentially toxic chemicals in the work environment. Continuous study and vigilance is required to determine their health effects and develop means for their control.

In addition to these new problems, we must not lose sight of the older hazards that continue to plague us. Two of the best illustrations are silicosis and lead poisoning. Although much has been accomplished through dust-control measures, silicosis remains the most significant occupational disease in the United States in terms of disability and compensation costs. Likewise, in the lead industries, despite numerous studies and the development of effective control methods, cases of lead poisoning occur every year. While large plants cannot be assumed to be free of occupational health hazards, a larger problem exists in the small plants and in the trades, where the hazards and methods for control may not be fully appreciated, rather than in the place of primary manufacture and use of chemicals.

Medical Developments

While changes in industrial technology present new challenges, advances in medical tech-

nology may be expected to provide some of the tools to meet these problems. Research on occupational diseases will undoubtedly gain momentum. Similarly, the massive research efforts to control the Nation's chief health problems hold special meaning for us, since 90 percent of industrial sickness absenteeism is believed to be of nonoccupational origin.

One approach is being made through studies to develop early, sensitive diagnostic techniques. In cancer, for example, studies are underway to apply the well-known Papanicolaou cytology technique for uterine cervical cancer to the detection of cancer of other sites. Some findings suggest that cytology can be useful in the early diagnosis of cancer of the genitourinary system. There is also hope for the development of effective anticancer drugs.

Heart diseases and related conditions are another major target. Studies in this area point, for example, to the development of an improved agent for the lowering of blood pressure in patients with hypertension. Considerable attention is also being given to reducing cholesterol, which some believe to be associated with atherosclerosis.

The benefits of some of the tools developed from this broad research may be compounded by applying them to occupational exposures. Thus, as an extension of the Papanicolaou technique, we have used bronchial washings to detect early cancer of the lung in uranium miners. In addition, work is underway to develop specific tests for occupational agents, to permit the detection and control of harmful exposure before irreversible damage occurs. Thus far, in our work in the Public Health Service, we have some indications that vanadium poisoning can be detected by changes in the fingernails long before any clinical symptoms appear. In support of better diagnostic techniques, work is also progressing in various laboratories to develop rapid analytical methods. Our own research, for example, has recently developed methods for the rapid determination of fluoride in urine, of cobalt exposures as evidenced by changes in blood serum, and a micromethod for blood lead determination.

As more sensitive diagnostic techniques are developed, we will be faced with the difficulty of equating concepts of physiological change,

as evidenced by these indexes, with the more traditional concepts of pathological change and possible compensable occupational damage.

With the advance of medical knowledge, we may also expect an increase in the number of diseases recognized as occupational. This increase would result from the greater recognition of an occupational factor in certain diseases formerly regarded as common to ordinary life, as well as the growing number of chemicals being introduced in industry.

In addition to improved recognition and detection of occupational diseases, we may look for further progress in their treatment. More recent therapeutic techniques, for instance, have used chelating agents in the treatment of certain illnesses. The chelating agents have the property of selectively removing certain metals from the circulation. For this reason, they have been found useful in treating metal intoxications, such as arsenic and lead poisoning. However, since such agents may also remove essential metals from the body, study has been needed of this possible hazard.

Sociological Developments

Against this background of change in industrial and medical technology, let us consider some of the sociological developments that influence health and safety needs. Unquestionably, the change in patterns of financing medical care is foremost. The vigorous growth of health insurance coverage reflects the conviction of the American public that the financial risks of illness need to be shared. To an increasing degree, such insurance coverage is being included in management-labor negotiations, so that both labor and management have a real concern about obtaining maximum medical care benefits at a minimum cost. At present, health insurance programs made available and paid for through the worker's place of employment cover more than 37 million employees and their 57 million dependents, a total of 94 million people (2).

The fact that management is increasingly obliged to bear all or part of the costs of illness, occupational or nonoccupational, has certain implications. The immediate effect has been to place increased emphasis on the prevention of

nonoccupational diseases, since these represent the greatest share of sickness costs and absenteeism. Another, and to us a more important, change may be anticipated. Up to now, it has generally been to management's advantage to deny occupational factors in the illness of workers so as to avoid compensation costs. However, as the costs of illness of all types become a management concern, we may expect a shift in this thinking. Management may logically come to view the early recognition of occupational factors as an opportunity to apply primary preventive measures and reduce the overall illness cost.

Another implication of management's concern with all types of employee illness is the possible tightening up of physical requirements for new job applicants. The degree to which this may be carried out is necessarily dependent on the labor supply. In the meantime, however, a very real problem involves the compensation aspects of employing workers with degenerative illness, such as heart disease.

A conservative estimate is that at least 5 percent of the working population has some form of heart disease. As a result of the cardiovascular diseases, an estimated 653,000 man-years are lost annually (3).

Numerous claims have been filed for heart attacks suffered during working hours, and there has often been a wide variation of medical opinion as to whether or not the heart attack was caused by the work. Because of the divergence of medical views, the heart case in industry has been a fertile field for litigation. All too often, cases have been tried on an emotional basis rather than on scientific fact.

In New York State alone, an average of more than \$4 million is paid every year for compensation of heart disease claims. This is 4 percent of the total amount awarded for all compensation claims each year (4).

Some action must obviously be taken if the millions of Americans with cardiac conditions are to be assured of continued employment. One possible solution may perhaps lie in the second injury fund, thereby protecting the final employer from the full brunt of the cost of a disabling illness.

Moving from this facet to the whole picture of workmen's compensation, we may expect to

see some changes here, too. The introduction of new hazards such as radiation, with long latent periods between the exposure and the appearance of damaging effects, is drawing more attention to the need for overhauling compensation practices in general and for correcting existing inequities.

Another problem calling for action relates to one of the basic goals of workmen's compensation—the rehabilitation of the occupationally disabled. We are seeing some progress in this area as the number of persons receiving help from public rehabilitation agencies and the number of those returned to productive employment increase each year. Last year, for example, 171,000 persons received rehabilitation services, and approximately 81,000 were rehabilitated to productive employment. However, our present inability to cope with the situation is reflected in the fact that some 250,000 persons each year reach the point of disability that requires rehabilitation, with an estimated reservoir of 2 million persons. Even more disturbing is the fact that, on the average, 9 years elapse between the time of disability and the time that rehabilitation is started.

A number of developments will be dictated by the changing age characteristic of our labor population. By 1965, the number of men and women in the labor force is expected to rise by 10½ million. Most of the increase will be in the 14- to 24-year-old group and in the 45-and-over age group (5). The increase in each group will be accompanied by its own set of problems.

The younger worker group generally is quite mobile and has a tendency to gravitate to the newer industries. The age and mobility of this group, combined with the long latent period for evidences of ill effects from certain occupational exposures, may well serve to cloak hazards inherent in those newer operations. Because of this and because some of the newer hazards could affect generations yet unborn in the families of exposed workers, we cannot wait for cases of illness to develop before taking steps to evaluate and control potentially hazardous exposures.

The problems of the older group will be felt in various areas. In the field of rehabilitation, for example, some accommodations may be necessary to meet the needs of an aging population.

Some have suggested extension of the present vocational goal of the program to also help people achieve a higher level of self-care.

Another sociological influence of this age factor is evident in the estimate that by 1975 the number of physicians' services needed because of chronic disease will increase by more than 50 percent (6). These demands of an aging population cannot but increase the problems associated with a growing physician shortage.

It has been estimated that merely maintaining the current ratio of physicians to population will require, by 1975, something like twice as many new medical school graduates each year as we now have (7). Pyramiding medical research needs may also be expected to drain off larger numbers of medical personnel. A consultant group to the Secretary of Health, Education, and Welfare, headed by Dr. Stanhope Bayne-Jones, estimated that by 1970 there would be a shortage of 6,000 medical researchers, as well as shortages of technicians, nurses, and other ancillary personnel.

The shortage of trained medical, nursing, and industrial hygiene personnel is also reflected in official occupational health agencies and in industry. Dr. Robert Kehoe has estimated that there is need for 10 industrial physicians and industrial hygiene engineers for every 1 now employed (8).

Industry, the health professions, educational institutions, and government may have to take another hard look at present educational opportunities and facilities to see how they can infuse them with a new vitality to meet these current and projected needs.

Training of additional personnel, we recognize, is only a partial answer. Better utilization of ancillary personnel may help conserve medical manpower and provide greater opportunities for service to the other members of the professional health team.

One means to accomplish better utilization and conservation is through the application of screening techniques. The value of screening techniques has been the subject of considerable controversy, but I believe that much of it is based on lack of understanding of their purpose and use. Screening examinations were never meant to be a substitute for physical examinations. Their value lies in extending

early detection services to persons who could not otherwise be expected to have the benefit of a physical examination. This value, however, can be realized only if adequate provisions are made for referral to the private physician for followup. There is no point to finding out that an apparently well person has an elevated blood pressure, a spot on the lung, or high blood sugar unless this condition is carefully investigated by a physician. Used properly, these examinations can serve as efficient detectors of disease in early stages, at the same time substantially decreasing the demand for and costs of medical and hospital services. I believe these techniques hold great promise for industry.

Since the shortage of professional personnel extends to governmental agencies, these groups, too, can effect better utilization of their personnel through closer working relationships between labor and health departments, compensation boards, and rehabilitation agencies. All too often, the administrators of these agencies within the same State do not even know each other's names. I am convinced that many benefits would accrue if the personnel of these agencies would become acquainted with each other and explore mutual problems and opportunities.

Such cooperative efforts would further contribute to the identification and more effective study and control of new occupational health hazards. At present, there are 76 official occupational health agencies in 40 States, staffed by 484 professional personnel. This staff reaches only 10 percent of the Nation's work force in any one year. This coverage can be greatly increased by a closer working relationship between the various agencies concerned with

occupational health and safety. By joining forces, we may be able to attack more successfully the absence of even the most rudimentary type of industrial hygiene program in over one-half of the industrial plants in the United States. In the face of a constant, growing stream of new hazards introduced by a changing technology, we must effectively multiply our efforts if only to stand still and not lose ground.

The total health and safety job confronting us is nothing short of gigantic. There is more than enough for all of us to do. And to the degree that we combine our resources and permit a cross-fertilization of ideas and experiences, we will make greater headway toward our mutual objective of worker protection.

Pushing Fish

To promote the eating of fish, Morocco's Ministries of Public Health and Interior sold fresh sardines at half price (7 cents a pound) for 2 weeks to some 100,000 dwellers in shanty towns on the outskirts of Rabat. Most of them have never tasted seafood and can afford meat only once every 4 or 5 months.

The Government's aim is to develop new food habits among those whose diet is deficient in protein, to show merchants how to profit from increased sales of fish at lower prices, and to stimulate the fishing industry which is operating below full capacity.

The ministries used press, radio, and movie publicity and broadcast from loudspeaker trucks such slogans as "One and a half kilos of fish is just as nourishing as one kilo of meat—and only one-fourth the price." Social workers set up stands in the shanty towns to demonstrate how to clean and cook sardines.

The Government plans to promote canned sardines in the inland areas where there is no refrigeration.

Morocco has a fishing fleet of nearly 2,000 trawlers and other boats which catch about 100,000 tons of fish, mostly sardines, a year. Many canning factories are closed because their products are not meeting price competition in foreign markets.

Hospital on the Amazon

Far up the Amazon, on Brazil's frontier with Colombia and Peru, at Benjamin Constant is the only hospital within 500 miles. A few patients are flown to the hospital; some arrive by river boat; but most are brought by paddling hours or days in the family canoe.

We make supervisory visits there only once a year. When I arrived at the hospital in 1957, about a year after it had opened, the X-ray machine was inoperative because of a grounded cable, the electrical connections for the hot water heater were not

completed, the oil burner in the kitchen was not functioning, and the flatwork ironer gave the employees shocks. The staff was anxious to learn, however, and soon, with adjustments, repairs, and instructions translated for the staff, nearly all equipment was working, and the hospital was functioning effectively.

When I returned a year later, accompanied by Dr. José Chaves, chief of medical services of the Amazon Program, all the equipment was still operational. However, an increased patient load was taxing the one doctor and one graduate nurse responsible for the care of both hospital and ambulatory patients. We offered suggestions as to clinic hours to permit more time for hospital patients and surgery and recommended to the Amazon Program Office of Serviço Especial de Saúde Pública that another doctor and graduate nurse be added to the hospital staff. The patient load, already so great that the present staff can no longer cope with it, will increase.

—KENNETH L. WINTERS, hospital administration consultant, U.S. Operations Mission, Brazil.

New Physicians for Indonesia

When 97 medical students were graduated from the University of Indonesia in August 1959, the new physicians, 21 of them women, took professional oaths according to their religions: Moslem, Protestant, Catholic, Hindu-Bali, or Buddhist.

The medical school of the university has collaborated with the University of California in the development of a new curriculum to increase the supply of physicians. (Indonesia now has about 1,000.) The period of training has been cut from 7 years to 6, with a new system of periodic examinations and clinical work integrated with theory.

Under a 6-year contract, the affiliation between the two universities was financed with \$1,900,000 contributed by the United States. In addition, the International Cooperation Administration provided \$900,000 to pay for advanced study in the United States for 125 students and \$500,000 to purchase equipment. Indonesia reported spending about \$6,250,000 for buildings, 10 houses for visiting professors, and administrative expenses. The University of California expects to start a similar affiliation in 1960 with the medical school at Airlangga University in Surabaya.

Synthetic Detergents in Well Water

JEROME DELUTY

THE presence of synthetic detergents, or "syndets," in ground water is being reported with increasing frequency, and the number of incidents may be expected to rise still more as housing developments are constructed in areas not served by either public water supplies or public sewers. A study in Suffolk County, N.Y., for example, found that many wells contained detergents (1). A committee has been formed by the Research Steering Committee of the Association of American Soap & Glycerine Producers, Inc., to investigate factors associated with such pollution (2).

In Rhode Island, the department of health has since January 1959 found synthetic detergents in samples from 72 wells in various localities in the State. These detergents were first noticed by the formation of a soapy foam in the bottle upon shaking, and their presence was confirmed by laboratory analysis. The presence of syndets in all these wells was believed to have resulted from their leaching through the ground into the ground water. Unlike soaps, which are precipitated by the calcium and magnesium in the water and left behind, synthetic detergents are only partly removed by a septic tank and absorption field. They are very stable chemicals and will travel appreciable distances through the ground into the water table and move with it.

The health department's analysis of well water, performed on application to the department, consists of physical examination, sanitary chemical analysis, and bacteriological examination. Specific tests include turbidity, sediment,

odor, color, nitrogen as free ammonia and albuminoid ammonia, nitrite and nitrate nitrogen, chloride, 20° C. and 35° C. plate counts, and coliform tests. Since January chemical tests for synthetic detergents have been performed routinely if the water appears soapy. A survey form, filled out by the collector of the sample, must accompany each sample. This form tells the type of well, its construction, and its location with respect to sources of pollution.

The following statistics pertain to the wells we have found to contain syndets:

- 47 percent were analyzed because of taste and odor complaints; 7 percent, because of foaming.
- 56 percent were positive for coliform group bacteria; 89 percent were considered grossly polluted on the basis of a sanitary chemical analysis.
- 21 percent were located in the cellar of the house.
- 44 percent were dug wells; 23 percent were driven wells; and 31 percent were drilled wells.
- 73 percent were within 50 feet of the sewage disposal unit; and 94 percent were within 100 feet of the sewage disposal unit.

Almost all these wells would be considered polluted on the basis of the chemical or bacteriological examination. If a well is so constructed and located that it is possible for it to be contaminated by the sewage disposal units, it is likely that syndets will be recovered from the well.

In certain areas, detergent contamination has been found to extend into most of the wells of a locality. One such area is the Quaker Hill Subdivision in Portsmouth, R.I., which consists of about 50 homes with no public sewers and no public water supply. This subdivision was developed during the period 1953 to 1958. The

Mr. Deluty is a chemist with the Rhode Island Department of Health. The paper is based on one he gave at the New England Health Institute, Providence College, Providence, R.I., in June 1959.

Analysis of 25 wells, Quaker Hill subdivision, Portsmouth, R.I.

¹Determined by methylene blue, given as parts per million alkyl benzene sulfonate.

NOTE: All drilled wells located in rock. Bedrock is 8-10 ft. below surface of ground.

house lots vary in size from 7,000 sq. ft. to 15,000 sq. ft., with the average lot being approximately 8,850 sq. ft. The individual wells are drilled through the overburden into Pennsylvania sandstone, shales, and conglomerates. Water is furnished through openings along bedding plains and openings in the zone of fractures. These homes have septic tanks and absorption fields for sewage and waste disposal, but as the lot sizes are fairly small, most of the wells are within 75 feet of the disposal unit.

A total of 25 wells in this area were analyzed, and all but 1 contained detergents. The amount ranged from 0.15 to 5.0 ppm (see table). Upon shaking, most of the samples showed a soapy foam, but several did not. The detergent level of those that did not appear soapy was in the range of 0.15 to 0.4 ppm. We have found that generally a syndet concentration of at least 0.50 to 0.60 ppm is necessary to cause a soapy foam; the higher the concentration, the more abundant and more persistent the foam.

Only 6 of the 25 wells showed any laboratory evidence of bacteriological contamination, and few exhibited high nitrogen values. The only form of nitrogen that tended to be abnormally high for this area was the nitrate nitrogen.

Many of the wells in this subdivision would be considered safe on the basis of routine bacteriological and chemical examination. Because of the presence of detergents, however, we have considered them polluted or potentially

polluted. Presence of detergents, if their concentration is high enough, is evidence that seepage from the sewage disposal field is finding its way into the wells. Under these conditions, the wells must be viewed with suspicion and considered polluted if the sanitary survey so suggests. For example, there would be no reason to question the safety of wells Nos. 2 and 3 on the basis of the bacteriological and chemical examinations. However, since these wells contain detergents and are located near the sewage disposal system, we feel they are unsafe and we recommend their abandonment.

The Rhode Island Department of Health, in its subdivision recommendations, has recognized the difficulties of maintaining safe drinking water and safe sewage disposal facilities in close proximity to each other. The department recommends lot sizes of at least 2 acres in areas where there are no public water facilities and a distance of at least 100 feet between any well and any sewage disposal unit.

A comprehensive community plan for meeting the problems of chronic illness, the result of 15 years of exhaustive study and experience in the Chicago area, is given in volume 22 of *The Proceedings of The Institute of Medicine of Chicago*, dated May 15, 1959.

Locally Oriented Health Careers Manual

WILLIAM J. MEYER, M.D., M.P.H.

PERSONAL interviews with several guidance counselors brought out the need for (a) locally oriented information about careers in the field of health, and (b) a sourcebook containing all the specific information, both scholastic and financial, useful to a high school student in deciding on a career consistent with the criteria of choice and ability.

Guidance counselors are busy people. It is impossible for them to check through their considerable library of source materials to find, for each student being counseled, detailed information on job descriptions, course requirements, institutions offering training in the career in question, academic costs, scholarship and other financial aid available, and all the other facts a young person needs to help him plan a career.

Early in 1958 the Glens Falls District Office of the New York State Department of Health undertook to provide these facts about careers in health in the form of a health careers manual. This decision was made because of the realization that, if the counselors were to be more effective in recruitment for health, they must have a better tool than any at that time available to them.

It is true that they had the excellent "Health Careers Guidebook," published by the National Health Council, and the other equally good recruitment materials published by the council and other agencies. However, the Guidebook was published in 1955 and certain parts of it, such as salaries and training costs, were already somewhat out of date; it also lacked specific information on financial aid and local sources of additional information, all important facts to a young person considering a health career.

Obviously, local orientation is impossible in a sourcebook designed for national distribution.

Guidance counselors are an important group in any program of career recruitment because they exert a significant influence on high school students' decisions. Like everyone else, they must perform their services within the limitations of the resources available to them. It is only natural that they will be more successful and will put a little more emphasis in those areas in which they have effective tools.

Therefore, it was decided to design a manual that would encourage the counselors to emphasize health careers. It was also decided to borrow material freely and to devise a book that would be easy to handle and simple to revise annually.

Format

The manual consists of 35 folders made from index paper, each containing a pocket on the left side. Front and back covers are of heavy, embossed fiber paper, and the book is bound together by a multiple-grip plastic binder.

Stapled inside the front cover are these instructions.

INSTRUCTIONS IN THE USE OF THIS MANUAL

This notebook has been designed with the hope of providing guidance counselors and students with a tool whereby they can obtain sufficient information to help them decide on a career in health. The format is such that any specific information can easily be found. For each health category there is also information on whom to contact for additional details.

The first section of the book consists of two lists of scholarships, neither of which is all inclusive. The first includes general scholarships which are available to high school graduates planning on entering the field of health (as well as other fields).

Dr. Meyer is district health officer of the Glens Falls District, New York State Department of Health.

The second list gives information on scholarships available in specific careers.

The rest of the book consists of a descriptive page for each health career, accompanied by recruitment literature which in most instances has been supplied by the officially recognized national or State association in each field. In a few instances there is no such literature because none is available. The descriptive page gives the following information under separate headings:

- The job
- Salary
- Opportunities
- Training needed
- Cost
- Schools (partial list of nearby schools)
- Further information (where to obtain)

The lists of scholarships, as mentioned above, are far from complete. However, it is hoped that annual revision of this notebook will be possible and that with each annual revision the scope of these lists will be expanded.

In listing the general scholarships for local high school graduates, an attempt was made to include information on those available through the schools specifically mentioned in the descriptions of the individual careers; however, the list is not complete. The list of scholarships available to local graduates for training in specific health careers is arranged according to particular careers. This list is national in scope and is more definitive than the general scholarship list.

The rest of the manual consists of 34 folders, each one devoted to a single career, although in a few instances one folder contains information on several related careers. Stapled on the right, inside each folder, is a 1-page, mimeographed job description sheet. The 40 careers described, including hospital careers as 1 group, are the following:

Administrator, public health	Medical technologist
Chiroprapist	Nurse, registered
Dental assistant	Nurse, psychiatric
Dental hygienist	Nurse, industrial
Dental laboratory technician	Nurse, public health
Dentist	Nurse, school
Dietitian	Nurse, practical
Hospital careers	Occupational therapist
Industrial hygienist	Optometrist
Medical librarian	Orthoptic technician
Medical record librarian	Osteopathic physician
Medical record technician	Pharmacist
Medical secretary	Physical therapist
	Physician
	Psychologist

Public health educator	Social worker, psychiatric
Radioisotope technician	Speech and hearing therapist
Research, health (chemistry, biochemistry, physics, physiology)	Statistician, public health
Sanitarian	Veterinarian
Sanitary engineer	Vocational rehabilitation counselor
Social worker, medical	X-ray technician

In the pocket on the left side of each folder are recruitment pamphlets obtained from the national or State headquarters of the official organization for a particular discipline. If no official organization exists for members of a specific discipline, recruitment material was obtained from more general sources such as the Hospital Association of New York State, the American Society of Clinical Pathologists, and the Public Health Service. This literature presents information that supplements and expands upon that given in the job description sheet. In a few instances these pockets are empty, because diligent inquiry failed to unearth any existing recruitment literature.

Plans for Revision

It is planned to revise the manual annually and to have the revisions in the hands of the guidance counselors in time for the second half of the school term when most vocational guidance activity occurs.

The format of the manual makes it easy to revise. Recruitment pamphlets can be changed merely by substituting new ones for old. Minor changes in the job description sheet can be inked in. If a revision is extensive, the old sheet can be discarded and a new one stapled in. It is equally simple to revise the two scholarship lists by inking in minor changes, substituting pages, or stapling in a complete new list. The revisions with an instruction sheet will be mailed to the counselors.

Discussion

When they first received the manuals, the local guidance counselors were enthusiastic. They were particularly pleased with its scope and local orientation and the fact that all the information was available in a single source.

After using it from January 14 to May 1, 1959, they received the following questionnaire:

1. Have you any definite knowledge that the manual has increased interest among your students in a health career? Yes — No —

2. If yes, what is your rough guess, *without consulting your records*, of any increase over previous years in the number of this year's graduating class planning to enter a health career? —

3. Now that you have had the opportunity to use the manual, has it been of value to you in your work? Yes — No —

4. Would you please list any suggestions you have for improvement of the manual.

The replies to these questions did not provide objective, quantitative data; the questionnaire was deliberately so planned because it was felt that if the people using the manual indicated its value to them, this expression would be sufficient to justify continuation of the project. Also, since guidance counselors are busy, no more information was solicited from them and compiled than was necessary to accomplish our purpose.

Twenty-three of the 28 school guidance departments answered the questionnaire. Seventeen answered "Yes" to question 1, five answered "No," and one stated the manual had not been in use long enough to determine.

The answers to question 2 included 12 positive statements. Five stated that it had stimulated interest in lower classes (10th and 11th grades). Six did not answer this question.

All 23 respondents answered question 3 affirmatively.

Answers to question 4 were as follows: 11 stated the manual to be excellent and needed no improvement, 1 suggested more "picture-type" folios, 1 wanted more empty pockets to hold additional material, 2 stated the manual should be kept up to date, and 1 wanted a smaller manual. Seven did not answer.

Collecting the material for the manual was a task of considerable magnitude. The most difficult job, however, was the process of selection. Much more good recruitment material is available than can be included in a volume of this type and still keep it to a size that is easily handled. The author found the health careers materials of the Empire State Health Council and the State Charities Aid Association of particular value. The pamphlets selected are purely a matter of personal judgment; other persons would undoubtedly make a dif-

ferent choice. The titles and sources of the recruitment literature inserted in the health careers manual are listed at the end of the article. Job description sheets had to be rewritten many times to achieve the desired degree of brevity, and many excellent leaflets and pamphlets had to be ruthlessly weeded out.

No claim is made to any originality in any of the material included in the manual. We borrowed freely. The only merit to the manual is that it is a compendium of much existing material and provides a single source for all the information a young person in this locality needs to help him decide on a future career in health.

There is no doubt as to the value of the local orientation of the manual. All scholarships originating within the health jurisdiction are listed; any scholarship whose restrictions make local students ineligible for it has been omitted. Finally, when the training is available from many schools, only those nearest at hand are listed. No information on student loans is included.

Creation of the manual is only the beginning of the district office's activities in recruiting for health careers. A number of local official and voluntary health organizations have an interest in this effort, and several have established active programs. It is hoped that an areawide health careers committee can be established to facilitate coordination of present activities and to stimulate a broadened program. Such an expanded program might include (a) extension of surveys of local opportunities in health careers, (b) expansion of the health careers programs presented in the schools, (c) health careers workshops for school personnel, and (d) a speakers bureau to supply schools with speakers who represent the various health professions.

Summary

A locally oriented health careers manual was created by the Glens Falls District Office of the New York State Department of Health and distributed to all school guidance departments within the health jurisdiction.

The value of this particular manual lies in its comprehensive format and its local orientation.

It supplies, within a single, easily handled volume, all the specific information needed by a high school student to help him decide on a career in the health field. The material is arranged for easy reference. Annual revisions can be incorporated with a minimum amount of effort.

The manual has been well received by local guidance counselors. They have expressed the opinion that it has proved of definite value to

them in their work, and that it is a useful instrument in recruiting more high school graduates for health careers.

The manual is the first step in the recruiting activities of the district office. Other possibilities for future efforts are suggested. They include formation of an areawide health careers committee and providing the schools with workshops, speakers, and additional programs to stimulate interest in the health professions.

Estimates of Acute Illness and Injury Among Children

Young children suffered acute illnesses with twice the frequency of adults during the year ending June 30, 1958, according to a report issued by the U.S. National Health Survey of the Public Health Service. The incidence rates for acute conditions involving medical attention or activity restriction ranged from an average high of four occurrences a year for children under 5 years old to a low of two for adults 25 years or over.

The report, which reveals the relative concentration of these illnesses and injuries—including everything from chickenpox and sore throat to appendicitis and broken legs—among children states that adults over 25 averaged 24.1 days of restricted activity from illness or injury per person during the year, compared with a range of 13.2 to 16.4 for age groups under 25.

Home accidents among children under 15 years of age were the chief cause of injuries restricting activity or requiring medical attention. They were an important cause, along with motor vehicle and work accidents, of restricted activity in the 15-24 age group.

The estimates are derived from interviews conducted for the National Health Survey by the U.S. Bureau of the Census with a representative sample of the civilian, noninstitutional population. The information recorded about individuals is confidential; only statistical totals are published.

The report is entitled "Children and Youth, Selected Health Characteristics, United States, July 1957-June 1958."

Prowazek Bodies in Trachoma and Their Epidemiological Significance

F. F. SYSOYEV

The original version in Russian appeared in *Vestnik Oftalmologii* (Journal of Ophthalmology), Moscow, March-April 1956, pages 3-9. Docent Sysoyev is head of the eye disease clinic of the Izhevsk Medical Institute, in Udmurt, A.S.S.R., R.S.F.S.R. The paper was translated in the Russian Scientific Translation Program of the National Institutes of Health, Public Health Service. It is presented here because of its interest to both ophthalmologists and public health workers.

THE DISCOVERY of bacterial carriage, the elucidation of the role of the human carrier in the spread of contagious diseases, and the development of epidemics are of exceptionally great importance.

At the present time, the carrier state has been studied and established for many diseases, for example, typhoid fever, bacterial dysentery, cholera, diphtheria, scarlet fever, plague, tularemia, brucellosis, pertussis, epidemic hepatitis (Botkin's disease), poliomyelitis, syphilis, tuberculosis, and in a number of ultravirus (N. F. Gamaleya), protozoan (various types of malaria), and other infectious diseases (I. R. Drobinskiy, 1953).

Trachoma has long been recognized as an infectious disease, and recent investigations have almost completely confirmed the virus origin of

it. The elementary bodies of the Prowazek-Halberstaedter intracellular inclusions are considered to be the only causal agents of trachoma (V. V. Chirkovskiy, M. P. Chumakov, Sh. D. Moshkovskiy, A. A. Arakyan, N. A. Zaytseva, A. L. Kankrov, P. N. Zhurin, Grosfel'd, P. Thygeson, Ishihara, and others).

We have set before ourselves the task of clarifying, by means of conjunctival scrapings for Prowazek-Halberstaedter bodies, the question of whether a carrier state exists in clinically healthy persons in foci of trachoma and in those who are clinically cured convalescents, that is, in stage 4 of trachoma.

In the literature available to us we have not been able to find much information concerning the detection of Prowazek bodies in the clinically normal ocular mucosa.

A. L. Kankrov (1928), who was a proponent of the specific nature of the intracellular inclusions in trachoma, noted the presence of trachomatous inclusions in the conjunctiva under certain conditions even in the absence of the clinical picture of trachoma. He observed that "when trachoma was present in one eye, intracellular inclusions were found in the scrapings of the other, healthy eye." "Could it be certified," he asked, "that their presence there is not the beginning of the disease, which has not yet manifested itself in any way?" (quoted by V. V. Chirkovskiy, *Vestnik Oftalmologii*, 1950, No. 3).

In her work (at the Trachoma Institute at Ashkhabad, devoted to the specificity of the Prowazek bodies in trachoma) Gorbunova pointed out that acute epidemic conjunctivitis produced by the Koch-Weeks, Morax-Axenfeld bacilli, and others were accompanied

in 13.7 percent of the cases by the appearance of the intracellular inclusions of Prowazek (quoted by V. V. Chirkovskiy, *Vestnik Oftalmologii*, 1950, No. 3). However, she did not report whether or not the clinical picture of trachoma developed after the conjunctivitis were cured. If not, then it is possible that in the given cases virus carriage existed, and the conjunctivitis exerted a provocative influence on the appearance of the Prowazek bodies.

Izabolinskiy and V. I. Spasskiy also speak of the presence of Prowazek bodies in the normal conjunctiva.

P. N. Zhurin (1951) examined 51 healthy eyes in 43 persons; of these, 27 persons had trachoma in only 1 eye. Prowazek bodies were found in conjunctival scrapings of five healthy eyes in five persons who had a disease in the other eye suspected of being trachoma, and in which Prowazek bodies were present.

The day after the Prowazek bodies were found, the healthy eyes became diseased in all cases, and after 2 days, a clinical, acute conjunctivitis developed, followed later by typical trachoma in both eyes. The author believes that the Prowazek bodies were found by him in the last few days of incubation, although this contradicts the data of Miyashita, who after an artificial transplantation of trachoma from person to person did not find Prowazek bodies in the incubation period.

Of the foreign authors, Bodian (1947) reported that out of 100 Fiji natives working for the American Army, signs of trachoma were found in 22 clinically. In 15 of these 22 persons, typical Prowazek bodies were found in the epithelial cells. Of 78 persons who did not have clinical signs of trachoma, 27 had inclusions morphologically identical with the inclusions found in the trachoma patients. Transmissibility and pathogenicity of the trachoma virus in these persons were not proved by the author, nor were the results of further observation of them described.

It is known that Prowazek inclusions are found most often in fresh trachoma or even in the prefollicular stage (Grosfel'd, G. Kh. Kudoyarov, and others) as well as in untreated trachoma. After treatment, they disappear or are found with great difficulty, and after therapy is stopped they can be demonstrated again.

In cicatricial trachoma they are very rarely found (V. P. Odintsov).

At the suggestion of V. V. Chirkovskiy (1953), trachoma in which the cicatrization of the conjunctiva has been completed, with no hyperemia or infiltration, is distinguished as stage 4 (absolute trachoma).

"Separation of the fourth period of trachoma into a special clinical form," writes V. V. Chirkovskiy, "is expedient for the purpose of characterizing the conclusion of the process, although, in essence, it is the same, third period of trachoma, the cicatricial. Establishment of its presence is important also in an epidemiological connection, because this period, in contrast to the others, is considered noninfectious by us."

Later, he mentions "that by the fourth period we understand not only those resultant forms of trachomatous inflammation where there is diffuse terminal cicatrization of the lids but also those cases where the trachoma has been concluded with the formation of individual scars, even though hardly noticeable, but where the conjunctiva does not show inflammatory signs."

According to the data of A. L. Kankrov (1928), in cicatricial trachoma (it must be assumed that this is the fourth stage, according to the modern classification) Prowazek bodies are rarely found.

In the literature available to us in recent years we have not been able to find any reports of investigations of Prowazek bodies in the fourth stage of trachoma.

In his work at the Chuvash Trachoma Institute, 1951, devoted to the problem of Prowazek bodies, P. N. Zhurin examined 1,039 trachoma patients admitted for the first time and in stages 1, 2, and 3, but apparently no investigations were carried out for Prowazek bodies in stage 4 trachoma patients.

From November 1952 through December 1954 the Izhevsk Medical Institute eye disease clinic examined 11 inhabited places with the aim of demonstrating Prowazek bodies both in trachoma patients and in clinically healthy persons. Trachoma patients in each of the four stages, persons suspected of trachoma, those with follicular and catarrhal conjunctivitis, as well as persons with clinically healthy palpebral conjunctivae were included.

For each inhabited place a special examination journal was kept on the type of the family-homestead list card. Each journal sheet was designed for a single family.

In order to obtain a surface scraping of the conjunctiva, the upper lid of the eye under examination was everted on a lid elevator, and in cases where the conjunctiva was contracted, even without the aid of the lid elevator, a conjunctival scraping was taken with a dull scalpel from the area of the upper edge of the cartilage and the plica semilunaris (superior fornix). In certain cases, depending on the picture of involvement of the conjunctiva, the scrapings were taken from the plica semilunaris of the lower lid (inferior fornix). The material obtained was spread out on a glass slide. From the material taken from each eye a single preparation was made. The scrapings were examined in the clinic laboratory. They were stained by the Romanowsky-Giemsa method, without fixation.

We classified the Prowazek bodies in groups as typical or atypical. Bodies with definite granulation in the form of caps around the nucleus of the epithelial cell belonged to the typical group. With respect to number, the bodies detected were classified as multiple, when there were two to three or more bodies in the microscopic field or in the preparation (in three patients with stage 4 trachoma there were three to four bodies in the microscopic field), and single, when after prolonged search only one or two Prowazek bodies were found in the preparation.

Prowazek bodies were considered atypical in which the granulation existed in the form of compact granular clumps disposed near the nucleus of the cell, or in cases of those bodies which were found in a stage of lysis.

P. N. Zhurin believes that "at the present time all the so-called atypical inclusions cannot be regarded as nonspecific substances, and one cannot avoid studying them and taking them into consideration in the evaluation of the problem of the etiologiical role of Prowazek inclusions."

We examined scrapings for Prowazek-Halberstaedter bodies in 2,933 persons. Of these, there were 53 persons suspected of trachoma, 13 with stage 1 trachoma, 19 with stage 2

trachoma, 491 with stage 3 trachoma, and 795 with stage 4 trachoma, 151 with catarrhal conjunctivitis, subacute and chronic, and 114 with follicular conjunctivitis. There were 1,297 clinically healthy persons.

On examination of the scrapings, Prowazek bodies were found in 3.8 percent of the persons suspected of trachoma. In patients who had trachoma they were found as follows: stage 1, in 23 percent; stage 2, 10.5 percent; stage 3, 9.49 percent; and stage 4, 4 percent. They were found in 0.7 percent of patients with catarrhal conjunctivitis, in 1.8 percent with follicular conjunctivitis, and in 1 percent of clinically healthy persons.

If account is also taken of the atypical Prowazek bodies found, the percentage of positive results is increased in all patients with the exception of the persons suspected of having trachoma and patients with stage 1 trachoma. The percentage of atypical bodies compared with typical ones was particularly high in clinically healthy persons: typical, 1 percent; atypical, 1.85 percent; together, 2.9 percent.

Of the 795 patients with stage 4 trachoma, 249 had been spontaneously cured, 271 had been treated in early childhood, 158 had been treated at intervals, and 117 had received systematic treatment.

Of the group of patients with stage 4 trachoma, antirelapse treatment had been conducted in only 168: of these, typical Prowazek bodies were found in 4 persons (2.4 percent). Of the 627 patients who had not received antirelapse treatment, there were more with typical Prowazek bodies, 4.55 percent. In the great majority of patients single Prowazek bodies were found, including those who had had a spontaneous cure, those treated in early childhood, those treated at intervals, and those treated systematically.

As had already been mentioned, of the 1,297 clinically healthy persons typical Prowazek bodies were found in 13 (1 percent); atypical ones, in 24 (1.8 percent). We wanted to clarify whether or not there was a difference in the percentage of Prowazek bodies found in contacts and in those who had not had contact with the disease. There was practically no difference—2.5 and 3.2 percent, respectively.

Data of an ordinary clinical examination with

the naked eye, or sometimes with the aid of a binocular magnifying glass, make it possible to decide that the trachomatous process had been concluded; nevertheless, as has now been established, foci of still-smoldering infection are found in a significant portion of the cases when they are examined by means of a slit lamp (N. Ya. Pokhisov, K. I. Golubeva, T. I. Voinova, T. D. Zatsepina, and others).

In order to clarify whether a state of cure of the trachomatous process existed, we (F. F. Sysoyev, N. T. Novoselova) checked 73 patients with stage 4 trachoma who were under the observation of the polyclinic group of the eye clinic. Examination was made of the conjunctiva and cornea by means of the slit lamp, and scrapings were taken for Prowazek bodies. In one of this group of patients the diagnosis of stage 4 trachoma was not confirmed by the slit lamp examination. No changes were found in the conjunctiva or cornea. He was healthy. No Prowazek bodies were found on two examinations of scrapings. There was no one who had trachoma in the family. In the other 72 patients, slit lamp examinations and examinations of scrapings were conducted once in 38, twice in 25, 3 times in 8, and 4 times in 1 patient.

In 30 trachoma patients complete cure had not occurred, and pathological elements were found in the form of small focal infiltrations and solitary follicles deeply situated in the tarsal conjunctiva. Of the patients in this group, Prowazek bodies were found in two. Often, cases were noted where the trachomatous process proved to be terminated in the conjunctiva of the lower lids, while there were elements of unhealed trachoma on the conjunctiva of the upper lids.

On repeated examinations of 30 patients with stage 3 trachoma no particular changes were noted in the clinical picture: the focal infiltration did not decrease, and the deep-seated follicles were not absorbed (6 months of observation). Stage 3 trachoma passed into stage 4 trachoma in only 1 patient.

Of 42 patients examined by the method of biomicroscopy, Prowazek bodies were found in 1.

Regressive or cicatricial pannuses of varying degrees of activity were found in all patients on examination with the slit lamp.

As has already been mentioned, out of the 2,933 persons, stage 4 trachoma was established in 795 by an ordinary examination, and Prowazek bodies were found in 45 of the 795 persons. Forty-three patients in whom there were Prowazek bodies were checked by the slit lamp at various periods after the first examination (6 to 24 months); of these, the trachoma remained unhealed in 19. Just as in the preceding group, small focal infiltration and solitary, deeply seated follicles were found in the tarsal conjunctiva (stage 3). Of the patients in this group, Prowazek bodies were found repeatedly in five.

Twenty-two persons proved by slit lamp examinations to be cured. Prowazek bodies were found repeatedly in two persons; two others had no signs of having had trachoma (healthy).

Therefore, of 116 patients in whom stage 4 trachoma had been established by the usual methods of examination, unhealed trachoma was found in 49 with the aid of the slit lamp; Prowazek bodies were found both in the unhealed and in the healed (convalescent carriage) cases.

Thirty-six persons who were clinically healthy but had Prowazek bodies were checked with the slit lamp; 17 proved to be completely healthy, 13 had stage 4 microtrachoma [very small trachomatous area], and there was 1 patient each with stage 4 trachoma, with follicular conjunctivitis, with folliculosis, with stage 3 microtrachoma, and with stage 3 trachoma. One was not accounted for.

Prowazek bodies were found repeatedly in two of the group of biomicroscopically healthy persons.

Two persons were checked for follicular conjunctivitis: in one a follicular conjunctivitis was shown; in the other, a *forme fruste* of trachoma. Of two patients with chronic conjunctivitis both proved to be healthy [with respect to trachoma]; in those with acute conjunctivitis, one proved to be healthy. In these patients it was impossible to find Prowazek bodies in repeated scrapings.

As has been mentioned, typical Prowazek bodies were found in 13 clinically healthy persons. On slit lamp examination, six persons of this group were shown to have healthy conjunctivae, while Prowazek bodies were found re-

which not only treatment of the trachoma patients remaining and prophylactic work will be carried out, but where also kolkhozniks will receive other forms of medical aid within the limits of competency of the nurse. Thus, gradually, with the elimination of trachoma, the trachoma stations should be reorganized as kolkhoz medical stations.

Conclusions

1. After establishment of the existence of stage 4 trachoma by ordinary methods of investigation, elements of unhealed trachoma remain in almost half of the patients in the form of small focal infiltrations and solitary follicles deeply situated in the tarsal conjunctiva or at the corners of the cartilages (stage 3).

2. Prowazek bodies are found even in those in whom the diagnosis of healed trachoma had been established biomicroscopically (convalescent carriage), which is of epidemiological significance.

3. In foci of trachoma the possibility of carriage of it by persons who are clinically completely healthy has not been excluded.

4. Patients with the so-called *forme fruste* of trachoma, latent trachoma, and microtrachoma are often recorded as healthy in ordinary examinations, but in practice are virus carriers. Therefore, the possibility of infection from them has not been excluded. Under certain conditions, the characteristic clinical picture of the disease can develop in them, diagnosable even by ordinary methods of examinations.

5. The criterion of the state of cure of trachoma, that is of complete safety for those around with a guarantee against relapses, has not as yet been established. Therefore, at the current stage of the fight against trachoma, registration and account of the healed cases (stage 4) and constant observation of them are obligatory, and antirelapse therapy is desirable.

6. The period of 4 to 6 months established for observation of the healed cases (stage 4) should be considered arbitrary. Systematic observation of them should be carried out without definition of periods of time.

7. In view of the relapses observed in those who have been cured, the trachoma (medical) stations in the trachoma foci should be maintained for a certain time even in the event all the patients are cured.

Grants for Evaluating Glaucoma Diagnosis Techniques

A 5-year study to evaluate methods for screening and diagnosing glaucoma in the United States has been launched with the financial support of the Public Health Service's National Institutes of Health.

Techniques currently applied to the detection and identification of glaucoma are now being evaluated at four research centers in this country through grants awarded by the National Institute of Neurological Diseases and Blindness. The grants are expected to total approximately \$115,000 a year.

The grantees are the Wilmer Institute, Johns Hopkins University Hospital, Baltimore; Moffitt Eye Hospital, University of California Medical School, San Francisco; Department of Ophthalmology, Washington University School of Medicine, St. Louis; and the Department of Ophthalmology, State University of Iowa, Iowa City.

The cause of the disease is unknown. Early detection might allow saving the patient's eyesight, but diagnosis in early stages is difficult because the patient often feels no discomfort. Since glaucoma appears to be a family disease, a large proportion of individuals studied will be children of glaucoma patients.

A statistical analysis of the study data is planned by the Chronic Disease Branch of the Service's Bureau of State Services.

STATEMENT

*By Arthur S. Flemming, Secretary of Health,
Education, and Welfare, April 20, 1959*

Accidental Poisoning

I want to call to public attention, and particularly to the attention of parents, data on accidental poisoning received by the National Clearinghouse for Poison Control Centers.

The clearinghouse, established in Washington by the Public Health Service in 1957, has now completed an analysis of 4,000 cases which came to the attention of local poison control centers between July 1956 and April 1958. Ninety percent of the cases analyzed involved children and were typical of the accidents that account for almost 500 child deaths and an estimated 600,000 nonfatal poisonings of children annually.

Children under 5 years of age represented 86 percent of the cases analyzed, the largest number being 1 or 2 years old. A study of the causes clearly indicates that American adults are not taking adequate precautions to protect children in a society that uses over 250,000 different kinds of drugs and household products, many of which are potential killers if misused.

A growing number of communities are establishing poison control centers to cope with poisoning problems. The first center was organized in Chicago in 1953 with support of the American Academy of Pediatrics. There were 130 centers in 1957, and today there are 260 operating in 42 States and the District of Columbia. (States that have no poison control centers listed with the national clearinghouse are: Rhode Island, Vermont, Louisiana, Nevada, Wyoming, Montana, Idaho, and Maine.) The centers maintain records of ingredients of trade-name products plus antidotes. This information is available to physicians by telephone day or night. Parents who call the

centers are given first-aid instructions and advised to call their doctor.

In 85 percent of the cases analyzed by the clearinghouse, children were under the supervision of a parent at the time the accident occurred; 10 percent were being cared for by other adults; and only 5 percent had been left in the charge of other children. How even a few minutes' negligence can cause tragedy is illustrated by the following cases:

A mother who left a can of cleaning fluid on the kitchen table while she answered the telephone returned to find her 2-year-old child had swallowed the fatal fluid. A grandfather put kerosene into an empty coffee can and was using it to clean car parts. While he turned his back briefly, his 16-month-old grandchild swallowed a small amount and died 9 hours later.

Evidence that the toxicity of common products is not generally recognized is the fact that many parents delay hours and even days in seeking treatment for children whom they know have swallowed drugs or household products.

For example, one of the fatalities, an 18-month-old child who swallowed iron sulfate pills prescribed for his parent received no medical attention until 2 days later. A delay of 6 hours in seeking medical care proved fatal for a 2-year-old child who swallowed a few grains of a cornmeal-sugar-rat poison mixture. The mother had put the mixture on the floor late at night and swept it up in the morning, but enough grains remained to kill the child.

Aspirin tops the accident list, accounting for a fourth of the cases studied, most of them small children who swallowed candied aspirin.

Prompt stomach pumping prevented serious consequences in most of these cases and there was only 1 aspirin fatality—a 2-year-old child who swallowed 35 tablets and died a day later despite prompt hospitalization and treatment.

Bleaches, detergents, soaps, water softeners, waxes, polishes, lighter fluids, cosmetics, insecticides, and herbicides as well as all types of medicines and drugs were among the products cited in the study as causing accidents of varying degrees of severity.

The three principal circumstances under which these products proved dangerous were: they were in old bottles or food cans instead of their original containers; they were not in their usual storage place; the storage place was not locked and was in reach of the child.

The place the accidents most frequently occurred were: the kitchen (41 percent of all cases); the bedroom (21 percent); and the bathroom (12 percent).

Most accidental poisoning could be avoided if parents of preschool children kept all products either under lock or out of reaching and climbing distance. Many serious consequences of poisoning could be prevented if parents called physicians promptly, without waiting for symptoms to appear.

Poison Control Centers

Most poison control centers are located in hospitals and maintain 24-hour telephone service, providing private physicians with information about the ingredients of trade-name products, antidotes, and other treatment. In most centers, inquiries are answered by a physician; nurses, pharmacists, or public health sanitarians handle inquiries in some; only 3 percent depend on clerks to relay information from the poison index cards which all of the centers maintain.

Emergency treatment is given in some cen-

ters, but their primary purpose is to furnish information to physicians. If a nonmedical person calls a center, he is given first-aid instruction and advised to call his physician.

The principal supporters of centers are State chapters of the American Academy of Pediatrics, State and city health departments, medical schools, and local medical societies. Some are also financed by parent-teacher associations and men's and women's service clubs. Frequently a number of organizations join together to provide financial aid, office space, personnel, and supplies. Children's Bureau grants-in-aid to State health departments also help to support some centers.

National Clearinghouse for Poison Control

The National Clearinghouse for Poison Control Centers serves local centers by providing information on new products which it obtains through a voluntary arrangement with manufacturers. Over 200 major producers of drugs and household products inform the clearinghouse of the ingredients their products contain and the antidotes for them. Since there is no law requiring that the ingredients of some of these products be printed on their labels—data which physicians must have in order to give proper treatment—the card indexes which the clearinghouse supplies to all centers are the chief source for such information.

The clearinghouse also receives reports of any new poison hazard discovered by any of the local centers and forwards the information to all other centers.

Additional activities of the clearinghouse include assistance to communities that wish to establish poison control centers, issuance of a monthly newsletter, tabulation and analysis of poison cases reported by the centers, and research.

Federal Publications

The Aged and the Aging in the United States. Hearings Before the Subcommittee on Problems of the Aged and Aging of the Committee on Labor and Public Welfare, United States Senate; 1959; 313 pages.

Statements and discussions by 22 expert consultants cover the health of the aged and aging; employment problems of the older worker and mandatory retirement; income maintenance and financing of medical care; and housing, living arrangements, and social services. Additional information includes reports, summaries of proposed legislation, 8 tables, and 10 charts.

Copies may be obtained by writing to Senator Pat McNamara, Chairman, Subcommittee on Problems of the Aged and Aging, United States Senate, Old Senate Office Building, Room 240, Washington 25, D.C.

The Dental Service Corporation in a Public Assistance Program. PHS Publication No. 680; 1959; 50 pages.

The dental care program of the Washington State Department of Public Assistance and its administration by the Washington State Dental Service Corporation are described. History, financing, eligibility and priorities for treatment, and dental fee schedules are discussed in detail.

Included in the appendix are copies of contracts between the corporation and the department and a complete set of tables covering the corporation's service for 1 year.

Health Manpower Source Book. Physicians, dentists, and professional nurses. PHS Publication No. 263, Section 9; 1959; 80 pages; 50 cents.

State, regional, and national data reveal trends in education, location, and specialization. They have been selected to provide background information for persons and organizations concerned with providing

health services and planning for the education of health personnel.

Tabulations relate to the 48 States and the District of Columbia except as otherwise indicated. Materials used in their compilation are identified on each table. Estimates to compensate for gaps in knowledge and to project findings to the future are included.

Health Statistics From the U.S. National Health Survey. Children and youth, selected health characteristics. United States, July 1957-June 1958. PHS Publication No. 584-C1; 1959; 43 pages; 35 cents.

The first of a new series which will carry health interview survey results for population groups, this report presents statistics on a variety of health topics among persons under 25 years of age.

Summary information is presented on acute conditions, persons injured, impairments, limitation of activity and mobility, disability days, hospital discharges, visits to the dentist and physician, and population estimates.

Arthropod-Borne Encephalitis. Procedures for investigating outbreaks. PHS Publication No. 674; 1959; by Roy W. Chamberlain; 27 pages; 20 cents.

Directed to doctors, veterinarians, and biologists, this field guide emphasizes obtaining materials for laboratory study. Instructions and lists of equipment are given for collecting and handling specimens from humans, horses, birds, and mosquitoes.

Staphylococcal Disease. A guide for organizing hospital inservice training programs. PHS Publication No. 692; 1959; 15 pages; 30 cents.

Directed to persons responsible for developing training courses for prevention and control of staphylococcal disease in hospitals, the suggested curriculum should be useful

also in helping to resolve other infectious disease problems in patient-care institutions.

Establishing a training committee, developing and maintaining a program, and course content for various personnel categories are discussed. A list of training aids is included.

Public Health Aspects of Increasing Tetraethyl Lead Content in Motor Fuel. PHS Publication No. 712; 1959; 49 pages; 30 cents.

The report of the Advisory Committee on Tetraethyl Lead to the Surgeon General of the Public Health Service is presented. Information on the consumption of tetraethyl lead, health and environmental data, and statements on the technical and hygienic aspects of increasing the tetraethyl lead content of gasoline from the present maximum of 3 cubic centimeters to a new maximum of 4 cubic centimeters per gallon are included.

Proposed regulations from an earlier Public Health Service publication on the use of tetraethyl lead in gasoline appear in the appendix.

Speaking of Prepaid Dental Care. A glossary of terms. PHS Publication No. 679; 1959; 25 pages.

Definitions for nearly 200 terms are given in this pamphlet designed primarily for persons interested in developing dental prepayment programs.

This section carries announcements of new publications prepared by the Public Health Service and of selected publications prepared with Federal support.

Unless otherwise indicated, publications for which prices are quoted are for sale by the Superintendent of Documents, U.S. Government Printing Office, Washington 25, D.C. Orders should be accompanied by cash, check, or money order and should fully identify the publication. Public Health Service publications which do not carry price quotations, as well as single sample copies of those for which prices are shown, can be obtained without charge from the Public Inquiries Branch, Office of Information, Public Health Service, Washington 25, D.C.

The Public Health Service does not supply publications other than its own.

THE INCIDENCE OF ILLNESS IN A GENERAL POPULATION GROUP

General Results of a Morbidity Study from December 1, 1921, Through March 31, 1924, in Hagerstown, Md.¹

By EDGAR SYDENSTRICKER, Statistician, United States Public Health Service

The problems and aims of public health are still set forth almost entirely in lethal terms whenever statistics are used. We speak of an unfavorable death rate and measure success in a lowered mortality. The best indices which have been available of the prevalence of nearly all diseases are the fatal cases only; and our epidemiology is limited, for the most part, to statistics of deaths.

The reasons for this condition are fairly clear to every vital statistician and will not be discussed here. Of greater pertinence is the result of a prolonged dependence upon mortality statistics. The effect has been to foster a fallacious premise for public health work, namely, that a low death rate indicates the presence of health. Obviously it does not. We know that, on the contrary, an exceedingly unhealthy region may exhibit a relatively low mortality, as, for example, a heavily infested hookworm locality or a section abounding in malaria. Pellagra may be widely prevalent in a community without affecting perceptibly its general death rate or even increasing materially the number of deaths from the disease itself. Instances of the same sort could be multiplied. The ill health that is manifested in symptoms, in discomfort, in lessened vigor and efficiency, even in illness and suffering, is not reflected in the death rate, except for certain diseases, for any purpose practicable in preventive work.

FEBRUARY 13, 1925, pp. 279-291

Edgar Sydenstricker's summary of provisional results of the first household survey by the Public Health Service in Hagerstown, Md., lit the path for the use of morbidity data about the Nation's population, in addition to mortality data.

Governmental Aspects of Sanitation in the Urban Fringe

FLOYD B. TAYLOR, M.P.H.

THE PUBLIC HEALTH engineer in the State or local health department is in a position to assume leadership in attacking the sanitary engineering problems of metropolitan or urban development. As so many of these problems concern the environment, a field in which he has professional competence, it is natural that he provide guidance and stimulation in obtaining for urban dwellers adequate water supply, sewerage, housing, health department inspection services, and other public health measures.

The public health engineer may be highly proficient in the technical aspects of sanitary engineering. However, in the nonsanitary engineering phases of urban area work, such as planning, economics, and governmental relationships, he is often in need of counsel. At a conference held by the Public Health Service in January 1958, the consensus was that the technical aspects of urban area sanitary engineering were becoming known but that the non-technical phases, such as governmental relationships and economics, were not well known and needed to be better understood by the worker in this field. It is upon these phases that progress in solving urban area problems hinges.

A case in point is found in the work of the Joint Legislative Committee on Metropolitan Area Study to the Legislature of the State of New York. In their appraisal of metropolitan problems in that State, water supply occupied

a prominent place. It was stated that planning, economics, and governmental arrangements were of more consequence than engineering solutions to the problem. They said: "Answers to these problems in a metropolitan area almost invariably entail governmental adjustments and working relations among various political subdivisions which are not in every instance readily achieved. Waterworks engineers have complicated formulas for measuring 'friction loss' in the velocity of water delivered through mains. There is also 'friction loss' in arriving at satisfactory governmental arrangements for water supply and distribution in metropolitan centers" (1).

The material which follows on the relationship of government to the urban fringe is intended to aid the public health worker by presenting the fundamentals of governmental relationships. References are given for further study. A question that may well be asked is, what place does a sanitary engineer have in establishing any governmental arrangement or change thereof? The answer is that although he does not usually have a direct role in shaping political circumstances, he may be influential in political decisions and he also may be, and frequently is, instrumental in obtaining the enactment of legislation. He may also be instrumental in obtaining cooperation between separate governmental groups. At the local level the public health engineer can become acquainted with the fundamentals of the governmental arrangement under which he works and the potential use of other arrangements. He can be thoroughly familiar with the purpose and content of various ordinances such as

Mr. Taylor serves as chief of the Special Studies Unit in the Technical Services Section of the General Engineering Branch, Public Health Service.

those that regulate housing, zoning, and subdivisions. At the State level he should be aware of all permissive and regulatory statutes which in any way affect the provision of sanitary engineering services to the urban area. This is also true of the worker at the Federal level.

Fundamentals

The relationship of government to urban fringe sanitation problems is best viewed in the light of the excellent fundamental concepts of government under which Americans live. These are that government has three functions: legislative, executive, and judicial. These three are closely bound together and interwoven, yet each is an entity.

Legislation is required to establish the legal framework within which urban area problems can be attacked. It is the medium for expressing the will of the people. Legislation is needed at the State level to authorize the use of local forms of urban area government as the State has sovereign power over the municipalities within its borders. Local ordinances are required to permit the adoption of governmental forms.

From the legislative proceedings stem the executive arrangements under which the method of choice or use is administered. These arrangements vary with the form used and will be discussed below.

Court action on contested legislation or executive decisions shape the plans chosen to deal with subsequent problems or in designing a new approach to solving a problem by the means first selected.

It must be recognized that urban fringe sanitation problems are a part of a larger problem of which the solution is primarily political. Hence the importance of understanding governmental functions. This larger problem is that of coordinating the actions of fragmented government—in 1957 there were in the United States more than 102,000 units of government (2)—operating in an area of such population density that political boundary lines do not contain the common needs of the people. Besides sanitation requirements there are the common needs of transportation, highways, schools, hospitals, fire and police protection, and storm

drainage. Sanitation requirements include water supply, sewage disposal, refuse collection and disposal, and health department inspection services in such categories as milk and food supply and service, radiation, and nuisances.

Governmental Arrangements

In the United States the following governmental arrangements have been used in recent years, singly or in combination, in dealing with urban fringe problems (3): annexation; extension of central city services; transfer of functions; special districts or authorities, single service and multiservice; city-county consolidation; incorporation; and mutual cooperation.

Definitions of these follow, along with a brief, tabulated description of the conditions which are favorable to a particular method, some of its advantages and disadvantages, and some locations where it has been used. The advantages and disadvantages pertain to the method described and are not necessarily considered from an overall standpoint such as the comparison of one method with another.

Annexation

Annexation is the acquiring by a governmental unit of additional territory adjacent to and outside its political boundaries. In practice it means moving a municipal boundary line to encompass more land. Sometimes a pocket of land called an enclave, entirely within a city boundary, but not a part of the city, is annexed (4).

CONDITIONS FAVORABLE TO THE METHOD

The area outside the core city should have no incorporated municipalities and must be immediately adjacent to the city boundaries.

ADVANTAGES

Total area subject to city taxes will increase.

Lowers cost of municipal services for annexed areas. City may receive larger share of State sales and gasoline taxes.

City codes may uplift housing face of surrounding area.

Prevents further fragmentation of government.

DISADVANTAGES

Promotes incorporation of unincorporated areas outside core city.

City may suffer a "net tax loss" if it has to provide

services at existing city rates and at increased cost caused by expansion of equipment and facilities.

Usually inapplicable where urban area crosses a county line and not at all where it crosses a State line.

Anneuxation laws may be difficult to use.

Seldom takes in the entire fringe so the problem may continue though smaller in area.

SOME PLACES WHERE USED

Mesa, Ariz., Milwaukee, Wis., Fairfax, Va., Alexandria, Va., Dallas, Tex., Kansas City, Mo., Louisville, Ky., Roanoke, Va., Tampa, Fla., Seattle, Wash., Wichita, Kans., Atlanta, Ga., Madison, Wis.

Extension of Central City Services

Extension of central city services refers to the core city's extension, usually through contract agreement with outlying areas or communities, of its water mains, acceptance of incoming sewerlines, or allowing use of its incinerator or sanitary landfill for disposal of refuse.

CONDITIONS FAVORABLE TO THE METHOD

Central city services, especially the waterworks, sewage disposal plant, or incinerator are of adequate capacity.

A definite limit can be set beyond which the city will not be expected to furnish services.

Adequate time for farsighted planning is available.

State statutes do not hinder effectiveness of this form of providing services.

ADVANTAGES

Do not need to build additional plants in outlying areas.

Do not need to set up another administrative and legal structure of government for outlying areas to handle sanitary services.

Urban dwellers avoid capital financing problems.

DISADVANTAGES

Many cities do not have adequate facility capacity for this method.

As existing systems tend to become smaller as they recede from the plant, it may be necessary to construct new water mains and trunk sewers with resultant high cost.

The suburb is completely dependent upon city for services without having a voice in their administration.

SOME PLACES WHERE USED

Grand Rapids, Mich., Auburn, Maine, Peekskill, N.Y., Bloomsburg, Pa., Aurora, Ill., Atlanta, Ga., Fort Worth, Tex., Rochester, Buffalo, and Syracuse, N.Y.

Transfer of Functions

In transfer of functions existing incorporated communities or State legislatures assign the

right and responsibility of providing services or functions, such as water supply and sewerage, to another order of government, frequently higher, such as the county. Transfer of functions may also occur laterally, that is from one community to another.

CONDITIONS FAVORABLE TO THE METHOD

A number of incorporated communities which will not consolidate politically.

An efficient functional operation at the level of government to which the transfer is made.

ADVANTAGES

Larger scale operation may produce more efficiency.

Per capita operating costs are lower due to single administration of operation.

County may be kept as a partner in administering functions common to many municipalities.

Community political boundaries remain intact.

DISADVANTAGES

People often fear surrender of any governmental rights from the local level to any other unit of government.

Not easily accomplished where a considerable number of city-type functions are transferred.

SOME PLACES WHERE USED

Dade County, Fla. (also called a federation type), and Los Angeles.

Special Districts

The special district is an independent administrative arrangement endowed with certain specified governmental rights. It may transcend political boundaries, has the power to issue bonds, sometimes to levy taxes, and to contract for construction, but is created for a specific purpose or purposes. It may provide either single or multiple services. It does not have political power of government outside of its specified purpose.

CONDITIONS FAVORABLE TO THE METHOD

Legal debt limits are reached in local communities.

Legal authority is granted by State legislation to establish districts.

Impossible to achieve informal cooperation between existing governments.

ADVANTAGES

May finance operations from revenue bonds.

Circumvents legal debt and tax limits.

Does not change any existing political boundaries.

Can be highly efficient.

Authority bonds may pledge only expected income and not property as security.

DISADVANTAGES

Authority bonds may carry higher interest rates.

Authority may grow to the point where it is non-responsive to the desires of the people it serves.

Adds another unit of government to existing maze.

When a revenue-producing function is given to an authority, existing governments lose that revenue.

SOME PLACES WHERE USED

North Jersey Water District; Washington Suburban Sanitary Commission (Md.); Allegheny County, Pa.; Sanitary Authority, Louisville-Jefferson County, Ky.; St. Louis, Mo.; Boston Metropolitan District; Passaic Valley Sewage District, Newark, N.J.; Akron Metropolitan Housing Authority, Akron, Ohio; Hampton Roads Sanitation District, Norfolk, Va.; Greater Greenville Sewer District, Greenville, N.C.

City-County Consolidation

The arrangement called city-county consolidation consists of constituting the county or the city as the single administrative, legal center for providing the essential common services and government required by urban dwellers. Neither city nor county completely loses its identity.

CONDITIONS FAVORABLE TO THE METHOD

A large city occupying most of the area of the county.

Equity in the relationship between city and county.

Action required due to expanded functions of both units in the same geographic area.

ADVANTAGES

Substantially eliminates dual governments.

Urban dwellers obtain services under one management.

Regarded by political scientists as one of the best answers to governmental difficulties.

DISADVANTAGES

Difficult to put into effect because of required State legislation.

Suburban dwellers fear they may be absorbed by the central city and fear assumption of added costs.

Not the answer where an urban area of more than one county is involved, also not the ultimate answer as urban areas cross county lines.

SOME PLACES WHERE USED

Philadelphia, Pa.; Boston, Mass.; New Orleans, La.; Baton Rouge, La.; New York, N.Y. (In recent years, only Baton Rouge in 1949.)

Incorporation

Incorporation is the establishment of a political unit of government with geographic bound-

aries in an unincorporated area, for a closely settled population.

CONDITIONS FAVORABLE TO THE METHOD

An unincorporated area of good size containing population densities of at least 2,200 per square mile.

Economic level of area is high enough to produce the tax base needed to finance the government and its functions.

ADVANTAGES

Resists city annexation.

Retains rights of the individual citizen.

Enables a group of citizens to establish tax basis for funds to provide services they desire.

DISADVANTAGES

Urban dwellers will probably pay higher taxes.

Taxes collected may not be adequate to finance improvements with result that services are ultimately inadequate.

May hinder the overall development of the area.

SOME PLACES WHERE USED

Dallas County, Tex.; Du Page County, Ill.; St. Louis County, Mo. Widely practiced except in the New England States.

Mutual Cooperation

Mutual cooperation is not a form of government. It is the working together of people in existing incorporated places with groups of people in unincorporated areas or with each other, within the existing legal framework, to accomplish the job of providing to all urban dwellers the common services they require.

CONDITIONS FAVORABLE TO THE METHOD

Legal obstacles to other forms.

The prior failure of other forms.

A spirit of cooperation among the people.

ADVANTAGES

Can function within existing legal framework.

No other layer of government is established.

No new taxes are imposed.

Possibly the best of all methods.

DISADVANTAGES

Inherent difficulty of getting groups of citizens to work together.

SOME PLACES WHERE USED

Tulsa, Okla.; Fairfax County, Va.; Metropolitan Area Regional Conference, Washington, D.C.; Salem, Oreg.; Los Angeles, Calif.

There has appeared on the North American continent another form known as federation. So far its use has been only in Toronto, Canada,

and in a modified version it has recently been established in the Montreal area. The Dade County, Fla., venture is sometimes called federation and some times functional transfer, under which it has been listed.

Under this system a new metropolitan government is established which generally has the territorial jurisdiction of the total of that of the lower orders of government. The lower orders of government continue in existence and have control over local functions. This method is related somewhat to functional transfer but with the important difference that many political rights of individual communities are surrendered to the larger government.

CONDITIONS FAVORABLE TO THE METHOD

A muddle of embattled incorporated-unincorporated fringe settlements.

State constitutional authorization can be obtained.

ADVANTAGES

Single control increases efficiency of operation.

Per capita cost of services is lower.

Community boundaries remain intact.

DISADVANTAGES

Some individual community rights are surrendered to a higher order of government.

Because of its vast size, quality of services may deteriorate due to logistical difficulties.

SOME PLACES WHERE USED

Toronto and Montreal.

In choosing, using, or advocating any of these arrangements, careful consideration must be given to three points: there will be resistance to changing any existing governmental pattern; the economics, tax structure, and bond market of any area is a key factor; land use and subdivisions should be carefully regulated.

Legislative

Legislation for the accomplishment of municipal government must be established at the State level and ordinances at the local level. Traditionally, the local government has won increasing autonomy from the State which, however, has never entirely relinquished its control over local governmental arrangements. Thus the establishment of a local governmental form is based upon State statute authorizing

this procedure. It is here, therefore, at the State level, that the foundations of the local governmental process are laid. For example, before an authority, annexation procedure, federation, or functional transfer may be established at the local level there must be enabling State legislation. Even the right of contiguous communities to cooperate with each other in providing services is sometimes regulated by State statute.

At the local level, municipal ordinance is invariably required to permit use of any governmental form and to delineate the provisions for administering it. Also State legislation will usually specify or control the administrative or executive procedure used by the local government.

A search was made to determine which States legally sanctioned which types of local governmental forms, and although no central summary was found some generalizations may be made. Many States permit incorporation and annexation under a variety of legal provisions. Among States having legislation authorizing formation of special districts are California, Colorado, Connecticut, Florida, Georgia, Illinois, Indiana, Kansas, Louisiana, Maine, Massachusetts, Michigan, Minnesota, Missouri, Nebraska, New Jersey, Oregon, Ohio, Pennsylvania, South Carolina, Tennessee, Texas, Utah, Virginia, Washington, and Wisconsin.

Constitutional amendments are usually needed to authorize consolidation, federation, or functional transfer, and exist in only a few States. Extension of central city services by contract with outlying areas is legal in many States.

Auxiliary legislative tools needed in coping with metropolitan problems are subdivision regulations (5), zoning ordinances (6), building and housing codes, and health regulations. A model subdivision regulation entitled "Suggested Land Subdivision Regulations" was published in 1952 by the U.S. Housing and Home Finance Agency. Forty-three States have enabling legislation authorizing municipalities and many counties to regulate land subdivision.

Examples of State-level legislation enacted to enable the provision of suburban sewers, one

phase of the urban area sanitation problem, have been described by Richards (?).

Federal legislation affecting urban area problems exists in the form of certain assistance programs. Also a variety of Federal programs of interest to the urban area worker are outlined in the U.S. Department of Commerce publication, "Federal Activities Helpful to Communities."

Executive

Except for the authority or special district governmental arrangement, the remainder of local forms are administered by traditional methods: commission, council-manager, and mayor-council. The mayor-council form is further described as weak-mayor and council, and strong-mayor and council (8).

These forms of administration have jurisdiction over all functions and responsibilities of the local government. Under them departments or divisions may be established to carry on the day-to-day work of providing the city with services. The department heads, of which the health director or commissioner is one, act as staff to the executive.

Commission

The people elect a commission, each member of which is made responsible for a section of the city governmental functions. The commissioner who received the most votes may be chosen by the commission as mayor. He is frequently made the head of the government and supervises the most important department. The commission may appoint heads of departments to execute their work. An example of the arrangement is shown as follows:

Council-Manager

Under the council-manager form the voters elect a council by popular vote. The council employs a professional municipal administrator or manager as its executive in handling the functions of government. He is an appointed,

individual who is subject to dismissal by the council, which retains the basic responsibility for proper discharge of the duties of government.

Weak-Mayor and Council

In the weak-mayor and council form the council and the mayor are each elected by the people. However, the mayor acts in an advisory capacity in matters of administration and is the government's political head. The council, sometimes through a series of committees, actually administers the affairs of the municipality. The council committees in turn run the departments.

Strong-Mayor and Council

Again, as in the weak-mayor and council, the people elect a mayor and council but under this form of government the mayor has direct charge of operating city functions. He may employ an executive to do the actual work, and a typical arrangement is as follows:

The various weaknesses and strong points of these forms are not discussed in detail as volumes on the subject have been written by political scientists and opinions differ as to their relative merits (8).

Under the authority or special district plan, an executive mechanism is established which has only specifically stated governmental jurisdiction (9). The administrative responsibility may be single or multiple in coverage. For example, some districts are limited to providing only water supply, and other districts are authorized to administer water, sewerage, and refuse jointly. The governing bodies of special districts or authorities are either elected or appointed. Members of the body, usually odd in number, may be called commissioners, directors, or trustees, and terms of office range from 2 to 6 years. The authority has the power to issue bonds, contract for construction, and collect service charges and sometimes to levy taxes. Dependent upon its size, the authority members may carry out their responsibilities directly, or they may set up a departmentalized administrative structure. An example of the latter is the Washington Suburban Sanitary Commission which has an organizational framework as follows:

Judicial

An extended consideration of the judicial aspects of the governmental problems in the urban fringe is beyond the limits of this discussion. Court decisions on cases pertaining to the subject are vast in number. In any given locality the worker in the field of urban area sanitation should learn the nature of judicial actions bearing upon his work.

One judicial procedure which varies from the usual is that in Virginia (2). There, since 1904, all annexation petitions are decided upon by a specially appointed circuit court whose judges are selected by the chief justice of the State supreme court of appeals.

A petition action can be accomplished in various ways. A community which desires to annex

land can pass an ordinance citing the need, proposed area for annexation, and the terms. If the people outside a municipality desire to be annexed, a petition may be made by 51 percent of the qualified voters of the area concerned.

Petitions are filed with the county circuit court and a special annexation circuit court is constituted. This court considers a petition on four counts: (a) the need of the community for more land in order to develop, (b) the need for governmental services in the territory to be annexed, (c) the mutuality of interests in the proposed annexed area and the annexing municipality, and (d) the financial ability of the annexing community to discharge its obligations to the residents of the area to be annexed. The court has the power to determine the boundaries of the annexed territory as well as the terms and conditions of the annexation settlement.

In making its decision the court often hears testimony from health officials, planners, and public administrators.

The most consistent use of annexation in this country has been in Virginia.

Summary

In summary, the governmental aspects of urban fringe sanitation are among the most important. They arise from the American system of the three foundations of government: legislative, executive, and judicial. The public health engineer, though not usually in a political position, should be thoroughly acquainted with these aspects and how to work through them. He also should be prepared to develop legislative measures which will facilitate his work.

The rate of admission to general hospitals in this country has increased by almost 80 percent in the last 20 years, from 56 to 99 admissions per 1,000 population, but the average patient in a general hospital today spends 8.6 days there—a decline of about one-third from the 12.5 average of 20 years ago, the Health Information Foundation reports on the basis of studies by the Public Health Service.

» «

In the present American population, chronic illness afflicts 21 million persons over the age of 55, according to estimates of the National Health Survey, Public Health Service. Of this number, nearly one-half are limited in their activity, and at least 1 in 10 is unable to work at ordinary tasks.

» «

A Korean physician, Chai Bin Park, received in June 1959 the first doctorate in public health in the field of biostatistics ever given by the University of California. His topic was "Longitudinal Studies of Tuberculosis Patients Registered in Hawaii." A summary of his doctoral dissertation appeared in the December 1959 issue, p. 1108, of *Public Health Reports*.

Home accident prevention is a public health activity in 40 States, reports the Home Safety Inventory of 1958, sponsored by the National Safety Council. Twenty-four States emphasize home accident prevention as part of established programs, and 16 additional States conduct short-term, specific projects in this field.

» «

Fifty victims of strokes each year will be treated completely within their own homes soon after the onset of attack by the Jewish Chronic Disease Hospital in Brooklyn, which has scheduled a 5-year program. Hospitalization may be required for an acute case, but the goal will be to return the patient home and supply all hospital services there. Rehabilitation therapy will begin at once. By starting treatment shortly after the stroke and the resulting impairment occurs, it is hoped that restoration will be supported and the effects of immobilization will be prevented. The validity of home treatment for other chronic illnesses will be evaluated as well. The project is supported by a grant from the National Institutes of Health, Public Health Service.

» «

A 3-year home care pilot project is underway in a rural area of North Carolina. Increased incidence of aged and chronically ill patients in Person County, covering some 20 square miles in the north central section of the State, stimulated the home care plan which is sponsored by the North Carolina State Board of Health and the Public Health Service. There are 11 practicing physicians in the county and one 60-

bed hospital, serving a population of 25,000.

Services now being given to patients in their homes include medical care and consultation, nursing, social service, physical and occupational therapy, health and nutrition education, orthopedic equipment, medicine, and sickroom supplies. Selected residents of all age groups who are chronically ill or disabled are eligible, regardless of financial status, if they possess the potential for self-care and self-support after appropriate restorative services.

The nucleonics industry is debating the Atomic Energy Commission's proposed rule amending its part 20 regulation, "Standards for Protection Against Radiation." The proposed amendment would decrease radiation exposure limits and require new cumulative exposure reports to employees. Complaints state the rule would complicate employee relations, impose unnecessary economic burdens, and seriously discourage industrial use of atomic energy.

Under the proposed changes, total external radiation exposure for any worker over 18 years of age would be limited to an average of 5 rems annually, reduced from 15 rems, with exposure in any one year limited to 12 rems. Maximum permissible concentrations of radioactive substances in air and water would be changed to be consistent with these dose limits. And licensees would be required to give employees a report showing accumulated exposure annually and within 90 days of termination of employment. Employers would also be required to give workers an immediate report of overexposure.

approach to ZERO for Tuberculosis

CONFERENCE REPORT

Poised for a knockout assault on tuberculosis, the Public Health Service and the National Tuberculosis Association last November invited a distinguished panel to advise on use of available resources for accelerating the disease's decline. Meeting at Arden House, Harriman, N.Y., November 29 through December 2, 1959, the consultants listed (p. 105) signaled a dramatic shift in policy and methods of tuberculosis management.

The following statements reflect observations of the views expressed by individual conferees.

The Goal

Tuberculosis can be extinguished as a public health problem. In favored settings, this eventuality is likely relatively soon. The region reaching from Wisconsin to the Pacific Coast already has an average tuberculosis death rate of 4.4 per 100,000, which, compared to a national rate of 40 in 1945, shows how far one large area has come toward eliminating tuberculosis. In a few smaller communities, the

This report was prepared in the Division of Public Health Methods of the Office of the Surgeon General and the Division of Special Health Services of the Bureau of State Services, Public Health Service.

disease has all but disappeared. For the Nation as a whole tuberculosis is a continuing threat, but the termination of this threat to public health is a reasonable social goal.

The Means

To reach this goal, what is needed is a common, popular determination and, in each community, a central responsible authority dedicated to the end that all cases of tuberculosis are treated by chemotherapy, either in public facilities or by private physicians, adequately and for sufficient time, in order to remove the public health hazard.

The Time

If the opportunity to end tuberculosis is not seized now, it may be lost indefinitely. Medications that are effective today must be applied broadly before the tubercle bacillus develops resistance to these drugs. Otherwise, in a susceptible population, the disease may rise again to a point which defies control.

The Scope

It is estimated that in 1956 about 800,000 Americans with tuberculosis needed supervision in the public health interest. About half this number were receiving such supervision.

While there is no entire State that can be said

no longer to have a public health problem in tuberculosis, the disease tends to be concentrated more heavily in a few States and in large cities. Within States and cities, it tends to be concentrated in some areas or neighborhoods. Of the race-sex groups, nonwhite males have the highest death rates, but more than half of all tuberculosis deaths (and nearly half of newly reported cases) occur in white males.

The disease is most frequent in the older population, which was generally exposed to the bacillus in years past. At age 50 today, the chances are about even that a person shows evidence of past infection. At age 80, prior infection is very likely a certainty. However, in white Navy recruits, aged 17 to 20, tested in 1958-59, only 1 in 20 had been infected. Although the rate of infection in young cohorts is very much lower than in older cohorts, about 2,600 new cases, not merely infections but cases, are reported annually in children under 5. And 18 percent of all new cases reported are in those under 25. The general trend toward a shift of tuberculosis deaths, cases, and infection into the older age groups appears to be taking place in all areas of the United States, whether tuberculosis rates are low or high.

The direction of tuberculosis control can be improved by information gained from records such as those recommended by the Working Group on Service Programs of the Public Health Conference on Records and Statistics in *Public Health Reports* April 1959, pp. 364-371. A well-kept case register enhances effective casefinding and treatment of patients with active disease.

Present trends indicate that, as the older population passes on, there will be fewer persons with infection, incurred in the past, that can break down into disease as a result of factors like malnutrition and other stresses. As there are fewer cases to spread infection, the number occurring as a result of new infection will grow progressively less, also. Assuming no disaster, depression, famine, or other tragic event reverses the trend, it is possible that tuberculosis will slowly die without increased effort at repression. But such an assumption is dangerous. Especially when means are at hand to deliver the coup de grace, aggressive action seems indicated.

The challenge is to find and disinfect patients with active disease or persons in a vulnerable category, especially those who once had active disease. This would include those who left hospitals against medical advice or whose treatment was otherwise interrupted, as well as selected patients treated prior to advent of chemotherapy. Although the main target is the reservoir of infection in active cases, known and unknown, special attention should be given persons in certain categories who are infected but do not have infectious disease, especially children entering adolescence and those under 4 years of age.

In view of the high probability of extrapulmonary complications from tuberculous infections in infants, effective chemotherapy for those with positive reactions to tuberculin tests should be prescribed without exception. At the same time, research should continue on the effectiveness of drug treatment in preventing tuberculous disease in other persons at special risk.

The Treatment

In the past few years it has become possible to provide effective medical treatment of tuberculosis to outpatients. Combinations of anti-tuberculosis drugs—applied adequately and without interruption—are capable of reversing infectiousness and curing tuberculosis in most patients. The cost of isoniazid in such treatment is about six cents a week, and other drugs used for combined therapy are not exorbitantly expensive.

Prolonged bed rest is not necessarily important in most cases. For the most part surgery is indicated less than in the past, thanks to the effects of chemotherapy.

Drug treatment of tuberculosis, good as it is, is not a simple matter of prescribing pills which are immediately and completely effective. It implies first the selection of an appropriate regimen, usually a combination of two drugs. The medication must be taken without interruption for many months. There must be determination of the patient's infectiousness at regular intervals, as well as of the activity of his disease. Those who do not improve under the prescribed regimen need a change of drugs, or may need hospitalization.

Conference Participants

Dr. Robert J. Anderson, Bertram Black, Dr. Lester Breslow, Dr. Richard M. Burke, Dr. A. W. Dent, Dr. René Dubos, John Egdorf, Kenneth Hamilton, Dr. Herman Hilleboe, Dr. Alexander Langmuir, Mrs. Lucille Petry Leone, Dr. Benjamin D. Paul, Dr. H. McLeod Riggins, Dr. Beryl Roberts, Dr. Joseph L. Robinson, Dr. Joseph B. Stocklen, Dr. William Tucker, and Dr. J. Yerushalmy.

Drug treatment of tuberculosis patients, as it is presently practiced, often falls short of the best that is available. Hospital patients leave against medical advice; patients at home stop taking drugs or fail to appear for medical appointments; long periods pass without assessment of patients' bacteriological or disease activity status. Because of these and other failures, the full potential of chemotherapy is not realized in a great number of cases.

The First Hurdle

The bacillus can be banished from the human environment if infectious cases are found promptly and treated adequately. All new infections are believed to result from fresh, vigorous tubercle bacilli coughed out by an infectious person. Usually infections occur before the case is found for treatment or when treatment is interrupted; the patient under treatment contributes little to the spread of infection.

Remarkably little is understood about the circumstances which favor infection. To illustrate the range of uncertainty, experience on a tuberculosis ward may be compared with the incident of a Christmas party. It is not unusual for a nurse to serve many months on an active tuberculosis ward without becoming positive to the tuberculin test. But an entire roomful of guests at a Christmas party once was found to have been infected in a single evening by one visiting seaman, the only active case in the lot. Research is needed in human factors of susceptibility to infection and in social factors in management of tuberculosis.

Fresh infections can be found and treated promptly with less trouble and expense if re-

search succeeds in developing an inexpensive, simple, and reliable tuberculin test, more satisfactory than those available today.

With present methods of testing and screening, casefinding is likely to be most effective if it is directed to selected populations in terms of the degree of their risk, such as: contacts of active or formerly active patients, adults over 45, especially males, and certain categories known to be vulnerable, especially children under 4, children entering puberty, or persons suffering from malnutrition, or living under congested conditions.

Casefinding as well as treatment and public health supervision of cases may be improved if the medical profession looks into the circumstances of patients whose tuberculosis is first reported on the death certificate. Of all known cases of tuberculosis in the United States, about 1 in 20 is first reported at death. Of all tuberculosis deaths, one in four is first reported as a tuberculosis case at death. About three-fourths of the cases reported are in a moderately advanced or far advanced stage.

Vaccination

Use of BCG, the only available vaccine, as indicated by recommendations of an advisory committee to the Public Health Service in 1957 and the American Trudeau Society in 1958, should be limited in the United States to certain highly exposed populations. Standards are needed for evaluating the activity of vaccines.

Strategy

Effective treatment of patients with infectious tuberculosis is the basis of plans to prevent new infections. Programs may proceed in several phases simultaneously, according to the prevalence of infection in defined neighborhoods or sections. Attention to the geographic strongholds of tuberculosis needs to have priority over campaigns of mass screening where incidence is relatively low. After the incidence of the disease is generally reduced, and if results of studies now in progress so indicate, attention may shift from therapy of diseased patients and investigation of suspect populations to the process of screening for positive reactors to be treated.

Ultimately, a single control officer may suffice for management of tuberculosis in large regions where infections are derived only from exotic sources.

Meanwhile, special funds should be allocated from central sources to concentrate the attack where infections are most common. Resources of personnel and facilities also should be subject to more central control.

The Personnel

The main burden of adequate treatment seems likely to be carried increasingly by the general practitioner in private practice, with help from the public health nurse and in some instances the medical social caseworker.

Because of the effectiveness of chemotherapy, treatment of tuberculosis more and more is managed by the general practitioner. Special instruction, consultation, and assistance by public health agencies can help private physicians to provide satisfactory treatment to tuberculosis patients. Additional services will help the patients and their families obtain assistance, as required, of the full battery of public and voluntary agencies. Such a unified program of treatment and services for all tuberculosis patients will require that physicians report without exception the cases under their care.

Cooperation of patients with treatment, especially if they remain at home under supervision, depends on attention given to their basic needs: food and shelter for the family, money for drugs and other expenses related to illness, suitable employment when they are ready, and ordinary friendliness. Remarkable cooperation has been won from patients simply by a demonstration that someone cared about them and felt it was important that they went through with the program of therapy planned for them.

In some communities, well-trained medical

social workers are available to see that patients and their families receive appropriate services. In most communities, the public health nurse has to see that the patients receive all available medical and social services they need without regard for lines of jurisdiction. In this task, the nurse is most likely to succeed if a single authority is responsible for assuring the availability and adequacy of all services to tuberculous patients, or if heads of independent agencies in the community at least meet regularly to exchange information and assistance.

Leadership

Criteria of performance and achievement, district by district, and State by State, and for the Nation as a whole, will expedite the victory at every stage. Public, voluntary, and professional bodies have the opportunity to establish such criteria for casefinding, diagnosis, reporting, treatment, rehabilitation, and surveillance. How much initiative will be taken in States and local communities toward setting criteria will depend to a great extent on the attitudes of the Association of State and Territorial Health Officers, the American Trudeau Society, and other professional bodies toward such local action.

It is largely their counsel which will determine whether communities will supply needed drugs and medical services, adequate diet, and homemaker services for tuberculosis patients. They can assure that adequate laboratory services will be available to all physicians.

Their leadership will determine whether political and social action will provide means for the integration of services and continuity of care for the tuberculous patient.

With effective leadership, it is possible that a program for eliminating tuberculosis as a public health problem in the United States can be brought far toward completion within the foreseeable future.

U.S. Army scientists investigate State regulations and processes of cleaning raw feathers for use in bedding and offer a practical disinfecting procedure.

Disinfection of Raw Feathers for Bedding Material

MORRIS R. ROGERS, M.A., ARTHUR M. KAPLAN, Ph.D.,
and GEORGE COHEN, B.S.

LARGE QUANTITIES of land and water-fowl feathers are used annually by the Armed Forces as filling materials in pillows and sleeping bags. Prior to use in these bedding items, the feather filling materials are simply "well cleaned, washed, and dried" according to military specifications (1-4). Although no exact procedure for cleaning, washing, and drying the feathers is outlined in these specifications, it is presumed that the feathers purchased over the past years were processed in accordance with the bedding laws of the State in which the feathers were purchased or in some instances according to the requirements set forth by the contracting officer purchasing the feathers for the Armed Forces. These procedures were apparently adequate to permit passing the feathers for cleanliness as required under these specifications. The cleanliness test consisted of determining the oxidizable matter (oxygen number) and solvent soluble matter, excluding DDT from the latter value.

The authors are associated with the U.S. Army Quartermaster Research and Engineering Center, Natick, Mass. Mr. Rogers is a microbiologist and Dr. Kaplan is chief, Fungicides and Germicides Branch, Chemicals and Plastics Division. Mr. Cohen is general engineer of the Textile, Clothing, and Footwear Division.

Forty-two States and the District of Columbia have enacted bedding laws which require, in addition to the cleaning, washing, and drying procedures, that all used bedding, and in many instances new bedding materials, must undergo some process to insure inactivation of all disease-bearing spores or disease-breeding germs, and removal of all filth, vermin, and extraneous organic matter. The final product is presumably clean and sanitary, but not necessarily sterile.

Various State regulations governing the sterilization of new down and feathers require the use of either dry-heat, hot water, flowing steam, steam under pressure, or fumigation. Answers to an inquiry addressed to three large eastern States indicated that very little research has actually been done on the sterilization of feathers. Similarly, little information has been published on the commercial sterilization of bedding materials by heat (5). The time-temperature relationships for the heat sterilization of feathers, incorporated into many State bedding laws, appear to be adaptations of the procedures used to sterilize mattresses and other bedding, with lower holding times specified in certain instances. A number of workers in the field have indicated that new feathers will be sterilized by current commercial processing. Data to support this view,

however, have not been available. Consequently, there appears to be little technical basis for the sterilization requirements of many State regulations.

Three diseases, salmonellosis, psittacosis, and histoplasmosis, transmitted to man from fowl, might be spread through the agency of feathers. *Salmonella* organisms of the types associated with salmonellosis in humans have been found in duck, hen, turkey, goose, and pigeon eggs (6-13). *Histoplasma capsulatum*, the causative organism of histoplasmosis, has been found in domestic fowl, soil, sawdust, and manure (14-17). Psittacosis has been reported in parrots, parakeets, lovebirds, canaries, chickens, turkeys, and pheasants, and the psittacosis virus has been isolated in garden soil (18-20).

It is most important to note that the literature does not establish any significant epidemiological or laboratory evidence that these diseases in humans are due to either exposure to or the handling of contaminated feathers.

However, since the organisms causing salmonellosis, psittacosis, and histoplasmosis in humans might be associated with feathers, the need for requiring sterilization of feathers procured for the Armed Forces has come under investigation. Although State bedding regulations use the term "sterilization," which can be interpreted as meaning disinfection, this is misleading since most feather processors do not actually sterilize feathers. Compliance would require the destruction of every form of life, be it plant or animal, visible or invisible under the microscope, harmful, or innocuous (21).

To avoid confusion over the use of the term "sterilization" in State bedding regulations, the position has been taken here that the sterilization requirement is not intended to insure sterile feathers in the finished article of bedding material but rather to insure the destruction of pathogenic contaminants of new feathers. If the word "sterilization" were taken literally, many feather processors would have to install new or modified equipment to meet the sterilization requirements stipulated in most State bedding regulations.

In the absence of experimental data, the purpose of this study was to determine the effectiveness of the washing, souring, and heat-drying operations in freeing feathers of potentially

hazardous micro-organisms, using laboratory, pilot plant, and commercial facilities. In addition, the effectiveness of a chemical procedure for disinfecting was investigated.

Methods

Washing and disinfecting procedures for raw feathers were tested and evaluated in the laboratory and, on a larger scale, in a pilot plant and a commercial feather processing plant.

Laboratory Studies

A general washing procedure (22) which closely resembles the procedure used in commercial feather processing plants was first evaluated in the laboratory to determine its bactericidal and fungicidal capacity. Sterile domestic white duck feathers obtained from a commercial source and inoculated with the test organism were used in the first series of tests. The feathers were first autoclaved for 30 minutes at 18 pounds pressure and then tested for sterility by plating a sample of the feathers in nutrient agar (Difco).

Escherichia coli, ATCC No. 26, and *Aspergillus niger*, QMC No. 458, were employed as test organisms. *E. coli* was grown in nutrient broth (Difco) at 37° C. for 18 hours and *A. niger* was grown at 30° C. on Sabouraud dextrose agar (Difco) for 6 to 7 days.

Three hundred and sixty-three grams, wet weight, of the sterile feathers were placed aseptically in a laboratory tumble jar and tumbled at 27 revolutions per minute with 1 gallon of water heated to 85° F. The sterile feathers were inoculated with 150 ml. of the broth culture of *E. coli* or 100 ml. of the pooled washings of two agar slants of *A. niger*. The jar was tumbled for 1 minute to permit thorough distribution of the tracer organism throughout the feathers. A 1-ml. aliquot of the inoculated feathers was removed aseptically from the tumble jar with sterile tweezers. The sample of feathers was allowed to drain free of excess water after expelling as much of the water as possible with tweezers. The 1 gram of inoculated feathers was transferred to a Waring Blendor and blended with 99 ml. of sterile water for 1 minute. A 1-ml. aliquot of the inoculated feathers suspension was then re-

moved and plated in nutrient agar or Sabouraud dextrose agar to obtain an organism count. Triplicate samples were tested which represented the controls used in these studies.

Fourteen grams of a trisodium phosphate blood solubilizer compound were added to the tumble jar and tumbled for 15 minutes. This was the end of the first wash cycle. One gram of the washed feathers was transferred aseptically to a Waring Blendor, macerated with 99 ml. of sterile water for 1 minute and plated in the applicable agar.

In the second washing cycle, the drained feathers were washed in 1 gallon of water at 85° F. containing 0.5 ounce of liquid nonionic detergent. The feathers were tumbled for 2 minutes, allowed to soak for 13 minutes with no tumbling, and drained. Bacterial counts on the feathers were taken in the usual manner.

The third and final cycle in the washing operation consisted of adding to the tumble jar 1 gallon of water at approximately 60° F., 22.4 grams of sodium silico fluoride, and 1,865 ppm of a general purpose disinfectant (23,24) having the following composition: 20 percent sodium-o-phenylphenolate, 40 percent sodium 4-chloro-2-phenylphenolate, 13 percent sodium 6-chloro-2-phenylphenolate, 14-18 percent moisture, with the remainder consisting of other isomeric phenolic compounds. The final pH was between 4 and 5, and water hardness ranged between 68 and 85 ppm as calcium carbonate. The feathers were tumbled for 15 minutes and soaked for 30 minutes in this solution. One gram of feathers was transferred to a Waring Blendor with 99 ml. of water and bacterial counts determined as previously described.

It was found in this and other unpublished studies that the need for incorporating a sorbitan monoöleate-lecithin in the agar was not required because of the small carryover of disinfectant in the dilutions used, coupled with the inactivating capacity of the peptone in the nutrient agar.

Tests were also made to determine the ability of the normal washing procedure combined with the use of the general purpose disinfectant, as previously described, to reduce or destroy the natural flora found on raw feathers.

The feathers used had not been autoclaved or inoculated with any organism prior to washing. Smears were made from representative survivor colonies which appeared on the agar plates using a simple alcoholic methylene blue stain.

Pilot Plant Studies

The washing and disinfecting procedure for feathers described in the laboratory studies was repeated on a larger scale in a pilot plant located in the U.S. Army Textile, Clothing, and Footwear Division at the Quartermaster Research and Engineering Command (22).

The procedure and water sources were essentially the same as in the laboratory runs except for the amounts of materials used in the tests. Six pounds of feathers from the same lot were placed in a washer which contained 35 gallons of water at 85° F. and 3.5 ounces of a trisodium phosphate blood solubilizer compound. The feathers were agitated for 15 minutes and then drained completely. The cycle was repeated using 35 gallons of water at 85° F. and 3.5 ounces of liquid nonionic detergent.

In a third cycle, the washer was refilled with 35 gallons of tapwater at approximately 60° F. to which 3.5 ounces of sodium silico fluoride sour and 9 ounces of general purpose disinfectant (1,865 ppm) were added with a final pH reaching about 5. The feathers were held in this solution for 45 minutes, rinsed twice with warm water at 85° F., and drained. Bacteria counts were made on the feathers after each washing cycle. The results are reported in the table.

Commercial Studies

The washing and disinfecting process was also evaluated on a large scale using the equipment in a commercial feather processing plant. The washer, similar to the pilot plant washer (22), except for capacity and materials of construction, was made of cast iron and consisted of a large drum 8 feet long and 4½ feet in diameter with rotating paddles mounted on a central shaft. It had a capacity of 125 pounds of dry feathers.

In the plant procedure, 125 pounds of raw white Long Island duckling feathers were dumped into a large washer containing approximately 500 gallons of water warmed to approximately 100° F. Sufficient liquid nonionic

detergent, or $\frac{1}{2}$ bucket, about 3 pounds, plus a scoop, or about 3 pounds, of alkali, and 1 cup, or about 1 pound, of sour, were put into the washer. No attempt was made to use exact amounts of alkali, detergent, or sour, since we desired to have the feathers washed with the normal variations expected under commercial processing conditions. The feathers were washed for 10 minutes and the washer drained. The feathers were then rinsed twice with water at approximately 93° F. for 20 minutes, fed into a centrifugal extractor to remove most of the water, and placed in a steam-jacketed dryer for 10 to 15 minutes.

The dryer is essentially a steam-jacketed cylinder with a series of rotating arms mounted on a shaft running along the axis of the cylinder. As the feathers begin to dry, they become airborne due to the action of the rotating paddles. The feathers are fed into the dryer cylinder through a sliding door at one end and removed by suction through a duct at the other end. During the drying operation, air is continuously removed through an exhaust duct at the top of the dryer. It usually takes about 15 minutes to dry a 50- to 60-pound lot of feathers.

Samples were taken at the feather inlet during the drying cycle. Information on the air-flow in cubic feet per minute through the dryer was not available. Temperatures were determined in the dryer by means of thermocouples placed at the feather inlet and outlet, the air exhaust, and near the bottom center of the dryer. Readings were taken at the beginning and at 1- to 4-minute intervals throughout the drying cycle. Representative temperature data are plotted on the chart. No temperature data is available from the thermocouple placed at the feather outlet since it was accidentally broken during the drying cycle. The bacteria and fungus counts on the raw feathers were also obtained before processing.

The procedure and conditions using the general purpose disinfectant were the same as previously described except that 8 pounds of the disinfectant, equal to 1,902 ppm in solution, were added to the feathers after the second rinse cycle and the feathers left in this solution for 45 minutes. Plate counts of organisms were obtained after 20- and 45-minute exposures to the disinfectant (see table).

Temperature variations in drying chamber at a commercial plant

All tests were performed within the plant where the air was dusty and filled with floating feather down. It was very difficult to prevent contamination under such conditions, especially during the sampling and plating procedures. These conditions could well account for the higher total bacteria and coliform counts obtained under commercial conditions in comparison to the laboratory tests.

Results

Results of the washing and disinfecting processes of feathers after each treatment cycle in the laboratory are reported in the table. The natural bacteria found on the feathers appear to be readily removed or destroyed by the three washing cycles, with the exception of the spore-forming bacilli. This is further substantiated by the nearly 100 percent kill obtained when sterile feathers were inoculated with *E. coli* and *A. niger*, used as tracer organisms. The nonpathogenic spore-forming surviving organism was identified as *Bacillus subtilis* by Dr. Ruth E. Gordon, Rutgers University, New Brunswick, N.J.

Four tests were conducted in the pilot plant. Organism counts were obtained only after the feathers had been washed and immersed for 45 minutes in a solution containing 1,865 ppm of the general purpose disinfectant. Although the percent kill (see table) in these tests was not as high as that obtained in the laboratory tests, all the nonsporulating organisms present on the feathers were completely killed.

A direct comparison cannot be made between the laboratory tests, and pilot plant and commercial runs, since the larger scale tests combined essentially three different wash cycles into one operation. Also, specialized media were used in an attempt to give a clearer picture of the types and numbers of organisms that survived during the washing, disinfecting, and drying procedures.

Percent kill of natural flora and inoculated organisms on feathers after washing and after disinfection with general purpose disinfectant under laboratory, pilot plant, and commercial conditions

Test runs ¹	Natural flora		<i>Escherichia coli</i> added		<i>Aspergillus niger</i> added	
	Percent kill	Counts per gram of feathers	Percent kill	Counts per gram of feathers	Percent kill	Counts per gram of feathers
<i>Laboratory</i>						
Control.....		5.0×10^4		3.49×10^5		9.0×10^6

¹ Laboratory and pilot plant tests made with domestic white duck feathers; commercial plant run used Long Island duckling feathers. Surviving organisms after laboratory and pilot plant runs were spore-forming bacilli.

² Tryptone glucose extract agar.

³ Eosin methylene blue agar.

⁴ Cooke's rose bengal agar.

⁵ Spreader on plates made it impossible to count.

Normal commercial washing and drying procedures reduced the total count of organisms by 64 percent, coliforms by 99.4 percent, and molds, 100 percent. The addition of 1,902 ppm of the general purpose disinfectant destroyed more than 99 percent of the nonsporulating bacteria and molds, with the exception of the 98.40 percent kill of coliforms after the 45-minute soaking. We believe this reduction in percent kill resulted from contamination of the plates by polluted air. As previously stated, the air was very dusty, making it difficult to maintain aseptic techniques.

Counts were not obtained of the total number of organisms after drying due to the presence of spreaders on the agar plates. Coliform and mold counts, however, were possible since the selective media used inhibited spreaders.

Data illustrated on the chart show considerable temperature variation within the chamber where the washed and disinfected feathers were dried. It should be mentioned that feathers are not static during the drying operation and that the temperature varied within the chamber between 113° F. and 165° F. at the end of the drying cycle. This means the feathers were going through a continuous heating and cooling cycle as they moved about in the dryer.

No obvious effects were found in the feathers after immersion in the general purpose disinfectant for 45 minutes and then drying. This was confirmed by the results of filling capacity and oxygen number determinations.

Discussion

The necessity for destroying the disease-producing organisms that might be found on feathers, such as *Salmonella*, *Histoplasma capsulatum*, and the psittacosis virus, can be considered a desirable public health requirement even though feathers have not been established as vectors of disease to the best of our knowledge. However, to require the destruction of nondisease producing organisms on raw feathers or to enforce sterilization prior to their use in bedding materials would appear to be costly, wasteful, and an exorbitant demand upon the commercial feather processors. Instead of enforcing sterilization, it would be much more realistic to require a pasteurization or disinfection

procedure which would kill all the pathogens.

Other workers (7,25) have shown that *Salmonella* is readily destroyed at 132° F. for 20 minutes and *H. capsulatum* at 131° F. for 15 minutes. Although no data are available on heat destruction of the psittacosis virus, other pathogenic viruses are inactivated at relatively low temperatures. For example, St. Louis and Japanese B-type encephalitis viruses are inactivated at 133° F. in 30 minutes, and the Russian Far East encephalitis virus is inactivated at 140° F. in 10 minutes. Types A and B influenza virus are killed by heat at 132° F. in 20 to 30 minutes. The variola or smallpox and yellow fever viruses are inactivated in 10 minutes by moist heat above 140° F. (25).

From the results of this study and the information available in the literature on the effect of heat on the destruction of the pathogenic organisms suspected to be associated with feathers, a specification requiring the three-cycle washing described in the laboratory test procedure followed by exposure of the feathers to 160° F. heat for 5 minutes, should adequately safeguard the public from a possible health hazard from feathers used in bedding materials.

An alternative disinfecting procedure to the heat treatment process is to immerse the feathers in a disinfecting bath solution such as the general purpose disinfectant. Previous studies sponsored by the Quartermaster Corps (23, 24) indicated that the general purpose disinfectant has a phenol coefficient of 71, which means that it is 71 times more effective in killing *Salmonella typhosa* than a 5 percent phenol solution. It is known (25) that 5 percent phenol will destroy *S. typhosa* in 5 minutes. The ability of the general purpose disinfectant to destroy this organism is therefore apparent. No data on the ability of the general purpose disinfectant to destroy *H. capsulatum* and the psittacosis virus is currently available. Stedman and associates (26) evaluated a mixture of 4-chloro-2-phenylphenolate, 6-chloro-2-phenylphenolate, and anhydrous potassium castor soap against *Trichophyton interdigitale* on inanimate surfaces and found a 99.0 percent reduction of the organism in 10 minutes. The mixture of 4-chloro-2-phenylphenolate and 6-chloro-2-phenylphenol-

ate has a reported phenol coefficient of 97 and further substantiates the fungicidal capacity of the general purpose disinfectant since it contains more than 50 percent of the sodium salts of these isomers. We have shown that a 100 percent reduction of mold spores has been obtained after 20 minutes soaking in the general purpose disinfectant.

It would appear, therefore, that the general purpose disinfectant has a powerful fungicidal capacity as well as germicidal efficiency. The only published virucidal data available on the action of phenolic disinfectants similar in composition to the general purpose disinfectant is a report on the virus of Newcastle disease, avian pneuencephalitis (27). This report showed that sodium-o-phenylphenolate with a phenol coefficient of 8, at 1.0 percent concentration, destroyed the virus in 5 minutes. Since the general purpose disinfectant has a phenol coefficient of 71, it is a more potent fungicide and virucide than sodium-o-phenylphenolate but a weaker fungicide and virucide than the mixture of 4-chloro-2-phenylphenolate and 6-chloro-2-phenylphenolate. However, soaking the feathers in 2,000 ppm of the general purpose disinfectant solution for 20 minutes should allow adequate time to reduce the pathogenic organisms to a safe level. This conclusion is based on the assumption that the fungus and virus susceptibility to the disinfectant does not vary greatly from species to species within each classification.

Summary

A study of regulations in 42 States and the District of Columbia governing the sterilization of feathers revealed great variety. Little or no technical data are available to substantiate some of the sterilization requirements, especially those pertaining to the sterilization of feathers by heat. Some requirements had little or no public health significance, others contained impractical or unnecessary provisions and still others differed markedly with respect to the same item of sanitation. The present investigation was undertaken to elucidate some of the problems confronting the U.S. Army in preparing specifications to assure that feathers purchased for use in bedding materials would

be acceptable by sanitation standards. A practical washing, heat-treating, and chemical disinfecting procedure for processing new feathers is described.

Training in Epidemiology

A course in applied epidemiology will be offered at the Communicable Disease Center, Public Health Service, Atlanta, Ga., May 9-13, 1960.

Designed primarily for physicians who serve as investigators of disease outbreaks or have administrative responsibility for such investigations, the course serves both as a refresher course for the experienced health administrators and as an introductory course for physicians new to public health. Emphasis is on developing an understanding of how epidemiological techniques can be used in the approach to the solutions of problems in the preventable disease field. Lecture-discussion sessions and audiovisual aids are used in the presentations, and there is much group participation which is obtained through the utilization of the group solution of epidemiological problems, seminar-type presentations, and panel discussions. Registrants will be expected to attend all sessions of the course.

Further information and application forms may be obtained from the Chief, Communicable Disease Center, Public Health Service, 50 Seventh Street NE., Atlanta 23, Ga., Attention: Chief, Training Branch.

Blood Sugar and Syphilis Serology Using a Single Specimen

JACK J. JOLLY, B.S., WILLIAM V. WHITE, B.A., JOSEPH PORTNOY, Ph.D.,
and JOSEPHINE W. GUTRIDGE, R.N.

SCREENING TESTS for diabetes and syphilis may be performed on a single blood specimen collected in a tube containing sodium fluoride, according to results obtained in recent studies.

Since the development of the Wilkerson-Heftmann method (1) using the Hewson Clinitron for the rapid examination of blood specimens for determination of sugar content, many health departments have used this testing method in mass diabetes screening programs. A number of health departments have combined diabetes screening with mass syphilis screening programs. The development of techniques for obtaining specimens for both diabetes and syphilis tests from a single venipuncture made the combination of the two screening programs economical and acceptable.

The most commonly used technique was reported by the District of Columbia Department of Public Health, and has been called the "piggyback" method (2). In this technique, a plain Sheppard tube is used to collect the specimen for serology; the needle of a second Sheppard tube containing sodium fluoride is then inserted into the rubber sleeve of the first tube to collect the specimen for sugar determination.

Mr. Jolly and Mr. White are health program representatives with Communicable Disease Services and Special Health Services, respectively, Region III, Charlottesville, Va. Dr. Portnoy, an immunoserologist, is with the Venereal Disease Experimental Laboratory, Chapel Hill, N.C. Miss Gutridge is a public health adviser specialist with Special Health Services, Region III.

The sodium fluoride prevents coagulation and preserves the glucose level for approximately 72 hours without refrigeration (3).

The Venereal Disease Research Laboratory (VDRL) slide test (4) was generally preferred for the serologic examination, and the Wilkerson-Heftmann method was used for sugar determination.

While the "piggyback" method was acknowledged to be more economical than previously used techniques, involving two venipunctures or drawing blood into a syringe and inserting the prescribed amounts into two test tubes, it still slowed up the collection of specimens for serologic screening and added to the cost of the screening program in personnel time and equipment. In addition, there was the traumatic effect on the screened of seeing the second specimen drawn.

In early 1957, the rapid plasma reagin (RPR) test for syphilis was developed by Portnoy, Garson, and Smith (5). During the same year, its acceptability for use as a rapid, practical, and economical screening test for syphilis was demonstrated by the Venereal Disease Branch, Communicable Disease Center, Public Health Service (6). More than 47,000 Mexican farmworkers, entering the United States through the border reception center, El Centro, Calif., were tested with the RPR test.

In the RPR test, the authors (5) utilized potassium oxalate, heparin, or potassium sequestrene as an anticoagulant. In diabetes screening programs, sodium fluoride in the approximate ratio of 10 mg. per cubic centimeter of blood has been a satisfactory anticoagulant and

Table 1. Comparative results of the RPR, VDRL, and TPCF tests, Chapel Hill data

Test	Number specimens	Reactive	Non-reactive	Diagnosed cases of syphilis			Sensitivity	Specificity
				Reactive	Non-reactive	Total		
RPR ¹	97	48	49	47	2	49	96	98
VDRL ²	97	42	55	41	8	49	84	98
TPCF ²	97	45	52	45	4	49	92	100

¹ On sodium fluoride specimen. ² On conventional blood specimen.

Note: Sensitivity = $\frac{\text{Reactors to test, confirmed as syphilitic} \times 100}{\text{Total diagnosed as syphilitic}}$

Specificity = $\frac{\text{Nonreactors to test, confirmed as nonsyphilitic} \times 100}{\text{Total diagnosed as nonsyphilitic}}$

glucose preservative when testing is not done immediately after collecting the specimens.

In studying the need for developing practical, economical, and rapid screening programs, it became apparent that the use of a single anticoagulant and preservative for both tests would simplify the collection of specimens and minimize the cost of conducting two screening programs.

Study 1

The Venereal Disease Experimental Laboratory, Chapel Hill, N.C., cooperated in a small pilot study to determine the feasibility of using sodium fluoride as an anticoagulant for the RPR test.

Ninety-seven sets of blood specimens were collected in a venereal disease prevention and control center, approximately half from diagnosed syphilitic patients, and half from undiagnosed screenees. The "piggyback" method was used, one Sheppard tube containing sodium fluoride, and the other containing no preservative. The following day in the experimental

laboratory, the RPR test was performed on the specimens containing sodium fluoride, and the VDRL slide test and the *Treponema pallidum* complement fixation (TPCF) test (7) were performed on the conventional blood specimens. The results of the study are shown in table 1. The diagnosis of syphilis was established or ruled out for every patient by means of a clinical diagnostic workup.

The results of study 1 indicated that the sodium fluoride tube yielded an acceptable specimen for the RPR test, making it possible to do combined syphilis and diabetes testing on a single specimen. In order to confirm the findings of this small study, results of the RPR and VDRL tests were compared on a larger volume of specimens under more typical field conditions.

Study 2

The Virginia Department of Health and the Richmond City Health Department participated in a study using specimens of blood obtained from the city jail population during April, May, and June 1958.

Table 2. Comparative results of RPR and VDRL tests, Richmond data

Test	Number specimens	Reactive	Number reactors diagnosed as syphilitic	Relative sensitivity	Relative specificity
RPR ¹	1,317	156	140	98	99
VDRL ²	1,317	107	100	70	99

¹ On sodium fluoride specimen. ² On conventional blood specimen.

Using the "piggyback" method, specimens were drawn into two Sheppard tubes, one of which had been prepacked with approximately 30 mg. of sodium fluoride. The conventional specimen was drawn into the plain tube, after which approximately 3 cc. of blood were drawn into the sodium fluoride tube. Specimens were examined in the laboratory of the Virginia Department of Health. The VDRL slide test was performed on the clotted specimens, and both RPR and sugar determination tests were performed on the sodium fluoride specimens.

Specimens from a total of 1,334 persons were tested by the VDRL and RPR methods. Of these, 1,157 were nonreactive to both tests and 177 were reactive to one or both tests.

Of the 177 persons with reactive test results, 143 were confirmed as having syphilis by a clinical diagnostic workup, and 17 were diagnosed as nonsyphilitic. The remaining reactors were lost to followup and therefore no definitive diagnoses are available for these individuals (11 were reactive to both tests and 6 were reactive to the RPR test only). These persons are excluded from the final computations. Comparative results on the remaining 1,317 specimens are presented in table 2. Diagnostic workups were not done on the non-reactors and since definitive diagnoses are unavailable for this group, the terms "relative" sensitivity and "relative" specificity are used.

The results of the Richmond trial tended to confirm the findings of study 1. The results indicated that the RPR test on sodium fluoride blood specimens was a more sensitive screening technique than the VDRL slide test on blood specimens collected in the usual manner.

Field Trial

Following the satisfactory results of the two controlled studies, the new method of collecting blood in the District of Columbia's diabetes and syphilis screening programs was used to replace the "piggyback" technique.

During June, July, August, and the early part of September 1958, 22,965 blood specimens were drawn, using the single prepacked sodium fluoride Sheppard tube. Specimens were tested in the District of Columbia Health Department laboratory for sugar content and serologic reac-

tion. The use of this technique proved highly successful.

It has been estimated that the reduction in the number of Sheppard tubes used and the saving of clerical and technicians' time amounted to a financial saving of at least \$7,092.65 for the collecting, processing, and reporting of the 22,965 specimens.

	<i>Savings</i>
Tubes -----	\$2,066.85
2 (GS-2) clerks-----	2,170.00
Technicians' time-----	2,755.80
Miscellaneous -----	100.00
Total-----	\$7,092.65

The D.C. Health Department laboratory reported the frequent occurrence of hemolysis. Apparently, however, this has not affected the accuracy of the results of the RPR test. Hemolysis can be reduced by gentle agitation of the tubes, and by running the RPR test as soon as possible after collecting the specimen. Extremes in temperature should be avoided and refrigeration should not be used unless specimens are to be kept more than 48 hours before testing.

Summary

Two studies were made to determine the feasibility of using sodium fluoride as an anti-coagulant in blood specimens collected for the rapid plasma reagin screening test for syphilis.

Study 1 consisted of testing two specimens each for 97 individuals. One specimen, without preservative, received the VDRL and TPCF tests; the second specimen, containing sodium fluoride, received the RPR test. The sensitivity rates for the three tests were: RPR, 96 percent; VDRL, 84 percent; and TPCF, 92 percent. The RPR and VDRL tests showed a specificity of 98 percent, and TPCF tests showed a specificity of 100 percent.

Study 2 compared results of VDRL and RPR tests on 1,317 sets of specimens (VDRL, conventional specimen; RPR, sodium fluoride specimen). The relative sensitivity of the RPR test was 98 percent, the VDRL, 70 percent. The relative specificity of the RPR test was 99 percent, the VDRL, 99 percent.

In the field trial, the District of Columbia

Problems in the Diagnosis and Treatment of Gonorrhea

WARFIELD GARSON, M.D., M.P.H., and GERALD D. BARTON, M.D., M.P.H.

THE LIMITATIONS and special usefulness of clinical and laboratory techniques in the diagnosis of gonorrhea are not well understood by the average practitioner today. Many physicians and clinics, because of complacency or lack of ancillary aid in diagnosis, employ measures for the treatment, management, and control of this disease which appear poorly justified in the light of newer research findings.

Diagnosis in the female is a major factor in both the clinical and control aspects of gonorrhea. It is generally assumed that the best procedures for the diagnosis in women is by smears and cultures taken from appropriate sites and correlated with clinical data. Studies by the Public Health Service utilizing the very best clinical and laboratory groups indicate, however, that clinical information plus smears and cultures result at best in the diagnosis of only 50 to 75 percent of those females having gonorrhea (1, 2).

Dr. Garson is director of the Venereal Disease Experimental Laboratory, Communicable Disease Center, Public Health Service, and research professor and head of the department of experimental medicine of the School of Public Health, University of North Carolina, in Chapel Hill. Dr. Barton is chief, Communicable Disease Center Services, Public Health Service, Region VII, Dallas, Tex. The paper was delivered at the 17th annual meeting of the United States-Mexico Border Public Health Association in Brownsville, Tex., April 1, 1959, and will appear this month in Spanish in the Bulletin of the Pan American Sanitary Bureau (World Health Organization Regional Office for the Americas).

This indicates that the most sensitive, practical indicator of gonorrhea in the female is the anterior urethra of a susceptible male. Such information should clearly point out the limitations in current techniques for diagnosis and place in proper perspective the importance of the epidemiological diagnosis of this disease. Certainly our control efforts cannot succeed if one out of every two to four women who have gonorrhea cannot be detected by current laboratory procedures and are available in the community as a focus for continued transmission of the disease.

Penicillin Susceptibility

There is a rather commonly held concept that the organisms causing gonorrhea and syphilis are similarly highly susceptible to the action of penicillin. While this is true concerning *Treponema pallidum*, it is not, and never has been, true for *Neisseria gonorrhoeae*. It has always taken more penicillin per organism to achieve a minimal inhibitory concentration (MIC) for the gonococcus than for the treponeme. Furthermore, the gonococcus has been observed to have a wide range of susceptibility to the action of penicillin, depending upon the strain of the organism tested.

During the period 1945-47 several investigators tested more than 200 strains of *N. gonorrhoeae* and found that all were inhibited by 0.05 unit or less of penicillin per milliliter. In 1955, however, Thayer and associates of the Public Health Service Venereal Disease Experimental Laboratory found that of 31 strains tested, only 78 percent were inhibited in this

Health Department initiated the use of the study technique (June 1958) and reported a financial saving of at least \$7,092.65 on the collecting, processing, and reporting of the first 22,965 specimens.

The use of this technique not only simplified the collecting and handling of specimens, but it also eliminated approximately half of the clerical work; and because of the speed and ease with which the specimen was collected, minimized the traumatic effect on the screened.

The results of these studies indicate that the sodium fluoride tube yields an acceptable specimen for the RPR test, thereby making it possible to combine syphilis and diabetes screening programs using a single blood specimen for both tests.

The method is recommended as acceptable, practical, and economical for use wherever it is desirable to do syphilis and diabetes screening on the same population group.

Milwaukee's Fluoridation Reduces Caries

A dental examination of 4,660 school children conducted by the Milwaukee Health Department following 6 years of fluoridation of Milwaukee's water supply revealed a significant reduction in the incidence of dental decay in all age groups, 5 through 13 years. Fluoridation levels were 0.9 parts per million in the winter and 0.7 parts per million in the summer.

The DMF index for a 7-year-old child was 1.29 prior to fluoridation and only 0.53 after 6 years of fluoridation, a reduction of some 59 percent in the amount of dental decay.

After fluoridation 8-year-old children showed decay in 46.9 percent of their 6-year molars; prior to fluoridation the comparable figure was 81.1 percent. Of the 6-year-old children entering the first grade this year, 31.0 percent were free from caries in their deciduous teeth; before fluoridation the percentage was 20.8.

During the 6-year period, the total cost of fluoridation was \$240,468. The total saving in dental care necessary for permanent teeth was approximately \$718,164. The annual per capita cost of fluoridation was estimated at 5½ cents.

A second study is projected 6 years from now after 12 years of fluoridation of Milwaukee's water supply.

Problems in the Diagnosis and Treatment of Gonorrhea

WARFIELD GARSON, M.D., M.P.H., and GERALD D. BARTON, M.D., M.P.H.

THE LIMITATIONS and special usefulness of clinical and laboratory techniques in the diagnosis of gonorrhea are not well understood by the average practitioner today. Many physicians and clinics, because of complacency or lack of ancillary aid in diagnosis, employ measures for the treatment, management, and control of this disease which appear poorly justified in the light of newer research findings.

Diagnosis in the female is a major factor in both the clinical and control aspects of gonorrhea. It is generally assumed that the best procedures for the diagnosis in women is by smears and cultures taken from appropriate sites and correlated with clinical data. Studies by the Public Health Service utilizing the very best clinical and laboratory groups indicate, however, that clinical information plus smears and cultures result at best in the diagnosis of only 50 to 75 percent of those females having gonorrhea (1, 2).

Dr. Garson is director of the Venereal Disease Experimental Laboratory, Communicable Disease Center, Public Health Service, and research professor and head of the department of experimental medicine of the School of Public Health, University of North Carolina, in Chapel Hill. Dr. Barton is chief, Communicable Disease Center Services, Public Health Service, Region VII, Dallas, Tex. The paper was delivered at the 17th annual meeting of the United States-Mexico Border Public Health Association in Brownsville, Tex., April 1, 1959, and will appear this month in Spanish in the *Bulletin of the Pan American Sanitary Bureau (World Health Organization Regional Office for the Americas)*.

This indicates that the most sensitive, practical indicator of gonorrhea in the female is the anterior urethra of a susceptible male. Such information should clearly point out the limitations in current techniques for diagnosis and place in proper perspective the importance of the epidemiological diagnosis of this disease. Certainly our control efforts cannot succeed if one out of every two to four women who have gonorrhea cannot be detected by current laboratory procedures and are available in the community as a focus for continued transmission of the disease.

Penicillin Susceptibility

There is a rather commonly held concept that the organisms causing gonorrhea and syphilis are similarly highly susceptible to the action of penicillin. While this is true concerning *Treponema pallidum*, it is not, and never has been, true for *Neisseria gonorrhoeae*. It has always taken more penicillin per organism to achieve a minimal inhibitory concentration (MIC) for the gonococcus than for the treponeme. Furthermore, the gonococcus has been observed to have a wide range of susceptibility to the action of penicillin, depending upon the strain of the organism tested.

During the period 1945-47 several investigators tested more than 200 strains of *N. gonorrhoeae* and found that all were inhibited by 0.05 unit or less of penicillin per milliliter. In 1955, however, Thayer and associates of the Public Health Service Venereal Disease Experimental Laboratory found that of 31 strains tested, only 78 percent were inhibited in this

lower range, while 22 percent required 0.1 unit or more per milliliter. Subsequent studies by Thayer and associates (1957), Curtis and Wilkinson (1957), and others have shown that from 20-30 percent of the more than 500 strains tested were inhibited only by the higher levels of penicillin (see table). Thus, over the past decade natural isolates of the gonococcus have indicated a definite and continuing proportional decrease in sensitivity to penicillin (3). In the United States, strains of the gonococcus inhibited by a minimal concentration of penicillin as high as 0.333 unit per milliliter have been observed; and, in the past few years particularly, more and more natural strains inhibited by minimal concentrations above 0.1 and 0.2 unit per milliliter. These higher MIC's exceed levels obtainable by usual doses of the type of penicillin given in the recent past in clinics throughout this country (4). Under these circumstances we would, of course, expect to see treatment failures on the basis of dose of drug alone, and, indeed, this is exactly what has been observed in a number of clinics where studies have been carried out to determine this and other factors in the treatment of gonorrhea (5-9). While the time-dose relationship is not so apparent in gonorrhea as it is in syphilis for successful treatment, it is an important factor in approaching the logical and effective use of penicillin. Observations by Thayer and associates have shown that the bacteriocidal effect of penicillin on the usual

strain of the gonococcus is detectable between the fourth and fifth hour of contact. From a practical standpoint such killing is usually complete by the 12th hour. Although a few strains tested on semisolid media were found to contain viable organisms through 24 hours of contact with penicillin, no strain has ever survived under these circumstances to 48 hours of exposure (10).

These investigators have also shown that cellular components can protect at least some of the gonococci from the action of penicillin. Using tissue culture techniques, it was observed that both HeLa cells and rabbit fibroblasts were capable of engulfing a certain proportion of the gonococci to which they were exposed. Further, it was demonstrated that penicillin, when applied to the medium, would kill extracellular gonococci but would not affect intracellular organisms. The presence of penicillin up to as long as 96 hours had no effect against the intracellular organisms, while at the appropriate MIC most extracellular daughter cells were killed within 5 to 12 hours. Inactivation of penicillin by penicillinase and changing either the osmotic relationships of the medium or disrupting tissue cells with engulfed organisms allowed for the recovery of the gonococci in a viable form on culture media up to as long as 240 hours thereafter. These recovered gonococci had the same MIC as the killed extracellular organisms. That the gonococcus is inevitably protected against all agents tested to

date under these circumstances has been shown by extension of this work to include not only penicillin but also a wide variety of antibiotic and chemotherapeutic agents (11).

Proposals

On the basis of these findings, Garson in 1956-57 proposed a working hypothesis for the treatment and management of gonorrhea which may be summarized briefly as follows (4).

- Sufficient penicillin must be given the patient so that the units per milliliter of serum will exceed the highest known MIC associated with any strain of the gonococcus in this country. Roughly, at this time, this would mean a serum level of 0.35 unit per milliliter.

- Such a level must be maintained in contact with the gonococcus for a period of at least 24 hours and preferably 48 hours. Based upon the laboratory in vitro work previously described, such time contact would allow for a complete bacteriocidal effect against any known gonococcus.

- Provisions should be made for treatment with very long-acting penicillin. This is necessary for two reasons: although 48 hours of exposure will kill all gonococci in vitro, we do not know when such exposure is liable to occur in vivo, particularly in the female. In other words, we could not treat a patient, obtain a 48-hour continuous penicillin blood level, and assume that the gonococcus in various foci in the female genitourinary tract had had an equal 48 hours of exposure. The second point is even more important. After being cured of gonorrhea, the individual may return to a milieu of venereal disease as a susceptible person and become reinfected in short order. It is possible with benzathine penicillin to obtain blood levels beyond 45 days in the human patient. While we do not know the exact minimum concentration of continuous penicillin that will protect an individual exposed to gonorrhea, it is known empirically that this system when applied does reduce the repeater load in venereal disease clinics.

This treatment is termed "antibiotic quarantine" by Dr. Ira Schamberg of the venereal disease clinics in Philadelphia, where he, as well as others, have demonstrated the effectiveness

of this approach in reducing repeaters in attendance (8, 9, 12, 13).

There is yet another factor to be considered in relation to the use of a long-acting penicillin. If it is true that, particularly in the female, certain tissue cells of the genitourinary tract are capable of taking viable gonococci within them and protecting such organisms from the effects of penicillin as has been demonstrated in tissue cultures, then with the dissolution of the host cell, viable gonococci are available for the autoinfection of the host. As such viable gonococci could be released some weeks after the initiation of therapy, it is obvious that the presence of long-acting penicillin in such a patient would be a deterrent to autoinfection. I must stress here that this is a hypothesis and has not yet been confirmed by clinical research. Nonetheless, until we know more about the disease in this regard, it behooves us to take such action as would prevent the likelihood of its occurrence.

Preston and Dunsworth in 1957 found that of 135 female patients treated with 600,000 units of penicillin aluminum monostearate (PAM), 24.4 percent yielded positive cultures 7 or 14, or both, days after treatment (7). In a second series of 65 such patients, the dosage of PAM was increased to 1.8 million units and the followup time was shortened to 3 and 7 days after treatment. In this series, only 4.6 percent yielded positive cultures. Two additional groups were tested to verify the finding that the dosage of 600,000 units of PAM was inadequate for a high percentage of cure. Of 77 women treated with 600,000 units, 16.8 percent yielded positive cultures during followup. Of 106 women treated with 1.8 million units, only 3.8 percent yielded positive cultures. If the number of probable reinfections is deducted, these authors estimate that the true failure rate with 600,000 units of PAM is 13 percent. They conclude that 1.8 million units of PAM is necessary for an acceptable rate of cure in females.

Hookings has used a treatment regimen consisting of a mixture of 600,000 units of PAM plus 1.2 million units of benzathine penicillin G. (5, 6, 13). His treatment schedule, applied in a rapid casefinding gonorrhea program, includes not only diagnosed early gonorrhea in women but also the prophylactic treatment of

all other women brought to observation; in addition, he has submitted men to this treatment schedule.

The results may be described briefly as follows: Using the attendance of diagnosed male cases as the criterion of success, the number of such cases was reduced by 18 percent at the end of 9 months and further reductions have occurred in subsequent experience. There was a decline also in the number of women who, having been named as contacts, were again named within 60 days. This decline was from 15 percent with the treatment previously employed (that is, 600,000 units PAM alone) to approximately 1.7 percent with the 1.8-million-unit dosage of mixed treatment.

In the light of today's knowledge, we must raise our sights in the treatment of gonorrhea to higher levels of penicillin extending over a much longer time period than has been used in the past (14). I believe it is obvious that the control of gonorrhea can be enhanced by the application of this knowledge in treatment. The epidemiologist can feel more secure that his patient will not be reinfected before he has the opportunity of finding source and spread cases, and he will have a longer effective period during which investigations may be conducted to bring contacts to epidemiological or specific treatment. Of greater importance, the tendency of the gonococcus to develop further resistance to penicillin can be blocked.

The problem of uncomplicated gonorrhea in the male is of course considerably less difficult in relation to diagnosis and treatment. In these days of the rediscovery of nongonococcal urethritis (NGU), it would be wise to take routinely at least smears on male patients to aid in the differentiation between gonorrhea and NGU. When occasional treatment failures of gonorrhea occur and NGU has been excluded, cultures should be obtained and the susceptibility of the gonococcus to penicillin determined to aid as a guide in therapy. It is perhaps worth while, too, to remind the epidemiologists that British, Danish, and American investigators have reported what appears to be cases of asymptomatic gonorrhea in the male (15-19).

For many years, it has been rather widely accepted that the endotoxin of *N. gonorrhoeae* responsible for the basic cellular pathology of

the disease, was a protein. Recently, however, Tauber and Garson have obtained a protein material from the gonococcus which is consistent with all past criteria referable to the endotoxin of the gonococcus (20). In an attempt to increase the toxicity and lethality of this endotoxin to animals and to purify the endotoxin for chemical characterization, they found that most of the toxicity could be related to nucleoprotein (21). By applying techniques unavailable to workers of the past, they were able to separate a previously unknown lipopolysaccharide phosphate from the protein endotoxin. The bulk of the toxicity was to be found in this phosphate rather than the nucleoprotein (22). If these new studies are confirmed, it would appear that the endotoxin of the gonococcus is not a protein, but rather a lipopolysaccharide.

This observation would be of extreme importance in relation to development of specific antigens for serologic testing for gonorrhea, as well as to the possible development of a relatively specific skin test for the disease. Further, as saccharide antigens are usually more closely related to protective immunity than are protein antigens, such studies may lead to a means of developing hyperimmunity in the host sufficient to protect against naturally acquired gonorrhea.

It appears we are once again upon the threshold of a renaissance in new knowledge about the gonococcus and gonorrhea. One of the many areas of findings being pursued is the exciting research concerning the adaptation of the fluorescent antibody techniques to the gonococcus, which could allow for the specific detection of gonococci in a stained smear within 30 minutes or the utilization of this technique for a serologic test for the disease (23). If this research is successful, it may be reflected in our clinical and public health practice in the not too distant future.

Quarantine Data

★ The number of people detained in ports of entry for medical observation in fiscal year 1959 increased nearly 400 percent, from 124 in fiscal year 1958 to 607 in 1959. This sharp increase was due largely to the outbreak of smallpox in Heidelberg, Germany, in December 1958.

★ The number of incoming travelers who were allowed to continue to their destinations in the United States but were required to be under medical surveillance for a time because of possible exposure to a quarantinable disease, increased more than 100 percent, from 58,083 in fiscal year 1958 to 117,310 in 1959. Most of these persons came from areas where there were occurrences of smallpox and yellow fever. In cases where the danger of exposure was serious, the Foreign Quarantine Service notified local health officials at the destination of the traveler.

★ In fiscal year 1959, 5,264,354 persons subject to quarantine inspection arrived in the United States, both aliens and returning citizens. This was an increase of more than 2 million over 1949.

★ In fiscal year 1959, there were 70,607 inspections of airplanes for quarantine or immigration-medical purposes, an increase of 50 percent over 1949. There were 33,271 inspections of ships, an increase of 37 percent over 1949.

★ The Public Health Service has increased its vigilance against yellow fever in two ways: control measures in the United States and cooperation with other countries.

To reduce the number of *Aedes aegypti*, the yellow fever mosquito, the Public Health Service has recently carried out a survey and control program at more than 100 international airports and dock

areas in the southern States, Hawaii, Puerto Rico, and the Virgin Islands, and at Mexican border crossing points. Highest "population index" was nearly 10 percent in Key West, Fla.; that is, mosquito larvae were found in 10 percent of the premises surveyed there. By an all-out campaign against the mosquito, the Key West health department reduced the index to less than 3 percent.

In Miami, the index at the international airport was 4 percent in July 1957. The Foreign Quarantine Service and the local health depart-

ment set out to reduce this index and was so successful that during a 6-month period in 1959, when the weather was most favorable to insect breeding, no yellow fever mosquitoes were found at the airport.

★ At the Mexican border, local crossings subject to quarantine inspection totaled an estimated 90,000,000; crossings from the interior of Mexico, 1,500,000; migratory labor examinations, 410,000. The staff numbered 124.

★ The 1959 Foreign Quarantine Service budget for activities at United States ports was \$3,950,869.

Fluorescent Antibody Tests for Detection of the Gonococcus in Women

W. E. DEACON, WILLIAM L. PEACOCK, Jr., ELIZABETH M. FREEMAN, AD HARRIS,
and WILLIAM L. BUNCH, Jr., M.D.

THE successful application of the fluorescent antibody (FA) method for the identification of *Neisseria gonorrhoeae* in men prompted an investigation of the use of this method for the detection of gonococcus in women. The preparation and use of fluorescein-labeled antiserums for the detection of the gonococcus in males was described in a previous publication (1).

Conventional culture procedures for *N. gonorrhoeae* identification in females, though recognized as superior to any other methods presently available, are slow, cumbersome, and costly in performance. Because of this, the culture method has been largely abandoned in many laboratories. The development of a more rapid, and a less complicated gonococcal detection method would therefore appear to have much to offer in future venereal disease programs aimed at the control of gonococcal infections.

In a recent study of gonorrhea in female contacts, Goldstein (2) found 16 percent positive by culture. Mahoney and associates (3) reported 21 percent positive in an examination of 2,429 women of the prostitute class. Stuart and Crookes (4) identified the gonococcus in 20.3 percent of 2,288 women examined at the main

venereal disease clinic of the Provincial Division of Social Hygiene, Edmonton. H. R. Morton found 47.4 percent of the female contacts in his study group to be positive (personal communication). From these and other reports (5), it may be concluded that the culture method, when performed under the most favorable circumstances, is capable of detecting the gonococcus in women in from 16 to 47.4 percent of the cases.

The aim of this study has been the development of a rapid fluorescent antibody procedure for *N. gonorrhoeae* detection, capable of obtaining equal or superior results to those reported for the culture method.

Materials and Methods

Female subjects, constituting the study group, were named contacts of men with gonorrhea seen at the clinic of the division of venereal disease control, Fulton County Health Department, Atlanta, Ga. The usual methods were used in performing pelvic examinations, and no special or unusual techniques were employed in obtaining specimens.

Direct Fluorescent Antibody Method

Specimens were obtained from three sites; the urethra, vagina, and cervix, by means of sterile, cotton-tipped applicator sticks. Slides were prepared in duplicate for smears from each site. Smears were fixed and stained for 1 hour at 37° C., and conjugates were prepared as described previously (1), except in the present study a 24-hour, heat-killed (100° C. for

Dr. Deacon is a microbiologist, Mr. Peacock and Miss Freeman are bacteriologists, and Mr. Harris is director of the Venereal Disease Research Laboratory, Venereal Disease Branch, Communicable Disease Center, Chamblee, Ga. Dr. Bunch is venereal disease control officer, Fulton County Health Department, Atlanta, Ga.

1 hour) *Aerobacter cloacae* culture (Jordan strain) was used for control and removal of free fluorescein. Conjugates which stained heat-killed *A. cloacae* smears were absorbed with an equal volume of saline-washed, packed cells. Absorption with an equal volume of saline-washed, dried beef bone marrow (Difco) was also used for the same purpose and with similar results. Leitz and Reichert ultraviolet light microscope assemblies were used for determining fluorescents. A desirable contrast between background and specific *N. gonorrhoeae* fluorescents was obtained by the proper selection of filters. A blue background was used to define the gonococcus in an intracellular position.

The recognition of *N. gonorrhoeae* by direct FA constituted a complete test or identification (fig. 1). Photomicrographs were recorded on Super Anscochrome daylight film using a basic exposure time of 5 minutes.

Delayed Fluorescent Antibody Method

Slants (30 mm. butt and 30 mm. slant) were prepared from Difco GC medium base plus hemoglobin and supplement B. This medium was placed in 15- by 125-mm. tubes sealed with culture tube closures B16 (?). Specimens were collected by means of sterile, cotton-tipped applicator sticks as described for the direct FA procedure. Slants were inoculated immediately after specimen collection by rotating and rubbing the swab over the surface of the medium. The stick was then broken so that the cotton swab remained in the tube, supported by the butt. After inoculation, slants were immediately placed in a candle-jar and held at room temperature until subsequent inoculations were performed from another patient, at which time the jar was again opened. After completion of specimen collections (4-6 hours), candle-jars were incubated for 16-20 hours at 35° C. Slant growth was mixed by the original swab left in the tube. This swab was also used to prepare heavy smears. These were allowed to air-dry. All delayed FA smears were fixed for 10 minutes in 3 percent formalin in phosphate buffered saline pH 7.2. This was followed by a distilled water rinse. Slides were finally blotted and allowed to air-dry. Subsequent staining with fluorescent

Figure 1. Identification of *Neisseria gonorrhoeae* in vaginal smear by the direct fluorescent antibody technique

antibody and microscope observations were the same as for direct FA. The demonstration of *N. gonorrhoeae* constituted the complete test (fig. 2).

Culture Method

The medium used for petri plates, the method of obtaining the specimen, inoculation and candle-jar procedure were as described under delayed FA. After plates were incubated for 24 hours at 35° C., they were examined for oxidase-positive colonies, and purification by replatings was instigated. CTA medium (BBL) plus 0.5 percent carbohydrate and 0.1 percent cornstarch was used for fermentation studies.

Results

Table 1 compares the direct and delayed fluorescent antibody methods with the conventional culture identification of the gonococcus. In the detection of individuals harboring *N. gonorrhoeae*, culture and the delayed FA procedures appear to be in agreement, each demonstrating 58 percent positive results. The delayed FA method, however, shows a higher degree of sensitivity in relation to total sites tested, 71 compared with 67 for the culture

Figure 2. Delayed fluorescent antibody method: Note on left heavy contamination as seen by tungsten illumination. On right-hand side is the same field under ultraviolet illumination showing well-defined gonococci.

technique. It will be noted in this regard that if culture alone had been used on cervical examinations, two individuals harboring *N. gonorrhoeae* would have gone undetected. Similar findings were also obtained in urethral examinations, 22 positives being detected by the delayed FA, and 20 by culture.

In contrast to the delayed FA technique, the direct FA procedure obtained positive results in 26 percent of all patients, or 41.4 percent of those proved by the delayed FA technique. In no case did direct FA demonstrate positive results without also obtaining similar findings by the delayed FA method. Invariably, when one or more sites (vagina, urethra, or cervix) were found positive by direct FA, two or more sites in the same individual were detected by the delayed FA method.

A further comparison of the direct and the delayed FA procedures is shown in table 2. As in the first series of patients, 58 percent of this group also demonstrated positive findings by the delayed FA method. Direct FA detected 24 percent of the individuals harboring *N. gonorrhoeae*. The delayed technique produced positive results in urethral smears in 38 percent of the patients, 44 percent positive were demonstrated from the vagina, and 46 percent from the cervix smears. If positive sites are

combined, vagina and urethra examinations account for 50 percent of the gonococcus detections, vagina and cervix for 55 percent, and a combination of all three sites for the highest result, or 58 percent.

Discussion

Direct FA identification of the gonococcus in females as demonstrated in this study may be accomplished in approximately 1 hour. It is obvious, however, that *N. gonorrhoeae* detection by this method is limited and dependent upon quantity of pathogens at the site at the particular time of examination. This effect is minimal when the delayed FA procedure is used. If one considers fluorescent antibody identification from the practical application standpoint, a saving of 3 to 9 days over the conventional culture procedures is effected. Other savings, of course, include the technician's time, culture media, and equipment.

One of the unexpected results was the high percentage of positive findings in vaginal examinations. Although culture findings (table 1) appear to be nearly equal to those demonstrated by the delayed FA technique, one must consider that cultures were performed under nearly ideal conditions. It should be empha-

Methods of Radiochemical Analysis. Report of a Joint WHO/FAO Expert Committee, Methods of Radiochemical Analysis. WHO Technical Report Series No. 173; Geneva, 1959; \$1.

International Pharmacopocia. First Edition, Supplement, Recommended Specifications. 1959; 224 pages.

Table 1. Comparison of culture and direct and delayed fluorescent antibody methods for identifying gonococcus, 50 female contacts

Method	Positive vagina		Positive cervix		Positive urethra		Total sites positive		Total patients positive	
	Number	Percent	Number	Percent	Number	Percent	Number	Percent	Number	Percent
Direct FA.....	13	26	4	8	5	10	22	14.6	13	26
Delayed FA.....	24	48	25	50	22	44	71	47.3	29	58
Culture.....	24	48	23	46	20	40	67	44.6	29	58

sized, particularly in relation to vaginal examinations, that culture results were obtained only through laborious platings and multiple isolation attempts prior to fermentation studies. Vaginal examinations (presumptive and confirmation by fermentations) frequently required 10 days or more for completion. This was also true for other examination sites where heavy contamination complicated *N. gonorrhoeae* identification.

The following are offered as well-defined procedures for the rapid identification of *N. gonorrhoeae* in females by the direct and delayed FA methods.

1. The greatest yield of positive findings may be expected if specimens from the vagina, cervix, and urethra are included in the examination. The vagina and urethra, as a combination will result in satisfactory findings, and may be used where complete clinic facilities are not available, such as examination table and speculum.

2. Duplicate smears from each site should be prepared. These are used for direct FA identification. At least one slant may also be prepared from each site and examined by the delayed FA procedure.

3. Direct FA slides demonstrating positive

results constitute a complete examination. Delayed FA needs completion only if the direct procedure fails to demonstrate gonococci. If desired, delayed FA may be used to confirm direct FA findings.

4. Fixation of air-dried smears (direct or delayed) is best accomplished by 10 minutes in 3 percent formalin in phosphate buffered saline pH 7.2. This is followed by a thorough washing in distilled water, and finally blotting before application of fluorescent antibody. Positive findings from any site constitute a completed examination.

Summary

Fluorescent antibody methods have been developed for the rapid identification of *Neisseria gonorrhoeae* in women. A combination of the direct and delayed fluorescent antibody methods was clearly demonstrated as superior to the conventional culture method. The delayed FA method gave a slightly higher yield of positive results in less time than the conventional culture method. The delayed FA method was superior to the direct method alone. The value of vaginal examinations in addition to the customary urethral and cervical tests is indicated.

Evaluation of tpcf-50 Test And Other TPCF Tests For Syphilis Diagnosis

HILFRED N. BOSSAK, WILLIAM P. DUNCAN,
AD HARRIS, AND VIRGINIA H. FALCONE

In recent years, the *Treponema pallidum* immobilization (TPI) test has become one of the most valuable laboratory aids in resolving problem cases in the diagnosis of syphilis. Because of its expense and complexity, however, its use has always been limited to a few large, central laboratories. The phenomenon of immobilization of *T. pallidum* in the presence of treponemal antibody and complement was first used in a serologic test for syphilis described by Nelson in 1949 (1). Since then, there have been continuing efforts by many workers to devise other procedures employing the *T. pallidum* as an antigen in serologic tests which might be more simply and rapidly performed, and which might serve as substitutes for the TPI test. Demonstration of an antibody in syphilitic serum which would agglutinate suspensions of killed *T. pallidum* (2), and the immune adherence phenomenon (3) resulted in the development of serologic tests (4-7) which used the whole, killed treponeme as an antigen. One of the most recent promising developments has been the application of fluorescent antibody techniques to the detection of treponemal antibodies (8).

The use of an extract of the *T. pallidum* as an antigen in a conventional complement fixation test was described by Portnoy (9) in 1955. This sodium desoxycholate extract was used in a modified one-fifth volume Kolmer test and was designated as the *Treponema pallidum* complement fixation (TPCF) test (10). The procedure (TPCF I) and an experimental

modification (TPCF II) were entered and performed by Portnoy in the Serology Evaluation and Research Assembly (SERA) Study (11). A second modification, referred to as the "tpcf-50" test, has recently been described by the same author (12), and is referred to as the preferred method, because of increased specificity and economy of time and reagents.

This report presents the comparative results obtained with the three *Treponema pallidum* complement fixation tests and the *Treponema pallidum* immobilization (TPI) test on serums from donors in selected patient categories.

Materials and Methods

A serum bank has been established at the Venereal Disease Research Laboratory, Communicable Disease Center, Chamblee, Ga., to facilitate evaluation of new serologic tests for syphilis or modifications of published methods. This bank is composed of serums from clinically categorized donors, and includes residuals from approximately 1,200 specimens which were included in the SERA study, in addition to serums from other sources. Convenient aliquots of unheated serum from these selected donors are stored in the frozen state and are drawn from the bank as needed.

The serums are classified in the following donor categories:

PRESUMED NONSYPHILITIC

- Apparently healthy donors presumably with no history of previous or present infection with syphilis.

SYPHILITIC

- Donors with primary syphilis proved by darkfield examination, who had not received treatment.

- Patients having had primary syphilis proved by darkfield examination and who had adequate treatment with 2,400,000 units or more of penicillin not less than 2 nor more than 4 years prior to time blood was taken.

- Donors with secondary syphilis proved by darkfield examination, who had not been treated.

- Patients with secondary syphilis proved by darkfield examination who had adequate treatment.

Mr. Bossak, Mr. Duncan, and Mrs. Falcone are bacteriologists with the Venereal Disease Research Laboratory of the Communicable Disease Center, Chamblee, Ga., of which Mr. Harris is director.

ment with 2,400,000 units or more of penicillin not less than 2 nor more than 4 years prior to time blood was taken.

- Donors with latent syphilis, adequately treated with 4,800,000 units of penicillin.

- Donors with clinical manifestations of late syphilis, such as paresis, tabes, aortic insufficiency, and aneurysm, adequately treated with 4,800,000 units or more of penicillin.

- Donors with late asymptomatic neurosyphilis or unspecified type of neurosyphilis, adequately treated with 4,800,000 units or more of penicillin.

- Donors with manifestations of late syphilis such as aortitis or unspecified type of cardiovascular syphilis, adequately treated with 4,800,000 units or more of penicillin.

WITH CONDITIONS OTHER THAN SYPHILIS

- Hospital patients with a variety of diseases or conditions, not receiving antibiotics and having no history or clinical evidence of syphilis.

- Patients 12 years of age or younger with yaws.

- Patients with pinta, below age at which associated syphilis might be expected.

- Leprosy patients not thought to have associated syphilis.

BIOLOGIC FALSE POSITIVES

- Patients with reactive nontreponemal tests, at least one nonreactive TPI test, and no clinical evidence of syphilis.

- Patients with reactive nontreponemal tests with no clinical evidence of syphilis and who had no previous TPI test.

Complement Fixation Tests

The TPCF I and TPCF II tests were performed according to the techniques described in the SERA study (11), and testing was accomplished at the Venereal Disease Experimental Laboratory, Chapel Hill, N.C.

The tpcf-50 test was performed at the Venereal Disease Research Laboratory in Chamblee, Ga., in accordance with the method described in the Manual of Serologic Tests for Syphilis, 1959 (13). Antigen for this test was furnished by the test author.

The TPI test was performed at the Venereal Disease Research Laboratory as described in the manual and was also referred to as "TPI-200" in the SERA study (11) conducted by the Public Health Service.

The TPCF I, TPCF II, and the TPI results on 1,208 SERA study specimens were taken from the SERA study report (11). The tpcf-50 test was performed at a later date at this laboratory on residuals of these same serums which had not been previously heated or tested and had been stored in the frozen state in tightly sealed containers since the original date of collection and separation of serum. The numbers of these specimens were coded so that the testing activity had no prior knowledge of the results obtained with the tests previously performed in the SERA study. An additional 263 specimens in the presumed nonsyphilitic category, which had not been included in the SERA study, were also tested in the tpcf-50 test. The TPI test was performed on all specimens in this group which were not nonreactive with the tpcf-50 test.

Results

The results obtained with the three *Treponema pallidum* complement fixation tests and the TPI test on 326 presumed nonsyphilitic donors are shown in table 1. The reactivity rates of the TPCF I (13.5 percent) and the tpcf-50 (13.8 percent) tests were almost identical, but were almost five times as great as were obtained with the TPI test (2.76 percent). The tpcf-50 test was also performed on an additional 263 specimens in this donor category, which were not included in the SERA study and reactive results were obtained in 15 in-

Table 1. Results of the TPCF tests and TPI test on presumed nonsyphilitics

¹ Including weakly reactive.

stances. The TPI test, performed on these tpcf-50 reactive serums, was reactive in two instances, weakly reactive in 1, and nonreactive in the other 12.

In primary syphilis, the tpcf-50 test was the most reactive of the treponemal complement fixation tests, and the TPI test was the least reactive of the four procedures (table 2). In untreated secondary syphilis, all four tests showed a high degree of reactivity, but in treated secondary syphilis, the TPCF II and the tpcf-50 tests were considerably more reactive than either the TPCF I and TPI tests, which gave identical findings. In latent and late syphilis, the tpcf-50 and TPCF I tests

were in close agreement but were consistently less reactive than the TPI test.

Results obtained in four categories of diseases other than syphilis showed the tpcf-50 test to be in closer agreement with the TPI than was the TPCF I test of hospital patients with a variety of diseases having no history or clinical evidence of syphilis (table 3). In yaws and pinta, all four tests were 90 to 100 percent reactive. In a group of 29 patients with leprosy, one reactive result was obtained with both the tpcf-50 and TPCF I tests and two with the TPCF II modification. No reactive results were observed in this group with the TPI test.

Table 3. TPCF and TPI test results obtained from donors with diseases or conditions other than syphilis

Category	Number of specimens	TPCF I		TPCF II		tpcf-50		TPI	
		Reactive ¹		Reactive ¹		Reactive ¹		Reactive ¹

Leprosy.....	29	1	3.45	2	6.90	1	3.45	0	0.00

¹ Including weakly reactive.

Table 4. TPCF and TPI test results obtained from donors classified as biological false positive reactors

Category	Number of specimens	TPCF I		TPCF II		tpcf-50		TPI	
		Reactive ¹		Reactive ¹		Reactive ¹		Reactive ¹	
		Number	Percent	Number	Percent	Number	Percent	Number	Percent
Nontreponemal test, reactive, TPI nonreactive	111	11	9.91	14	12.61	10	9.01	5	4.50
Nontreponemal test reactive, no clinical evidence	109	444	40.37	47	43.12	34	31.19	38	34.86

¹ Including weakly reactive.

All of two groups of donors classified as biological false-positive reactors were reactive in one or more nontreponemal tests in the absence of any clinical or anamnestic evidence of syphilitic infection (table 4). In a group limited to patients who were previously nonreactive in at least one TPI test, almost identical reactivity rates were obtained with the TPCF I and tpcf-50 tests (9.91 percent and 9.01 percent, respectively), but these were approximately twice that of the TPI test (4.05 percent). Although it might be expected that the TPI test would be completely nonreactive in this group because of the method of preselection of donors, the five TPI reactions obtained among these patients could be attributed to the fact that the procedure used in screening these patients may have been less reactive than the modification used in this study. Where the biological false-positive diagnoses were made by clinical impression without previous TPI test screening, all four tests were more reactive than among those who were not reactive to the TPI test, possibly due to the presence of syphilis, treated or untreated, in this group of donors. The TPI and tpcf-50 tests, however, were in closer agreement than the other two tests, in this last category.

Summary

The three TPCF tests and the TPI test were used on serums from donors in selected categories and results compared.

1. In the presumed nonsyphilitic group, the tpcf-50 test and the original TPCF were in close agreement. However, the reactivity rate

of both tests was five times greater than that of the TPI test.

2. In primary and secondary syphilis, the tpcf-50 test was either comparable to or more reactive than the TPCF I and TPI tests, but in latent and late syphilis, with the exception of neurosyphilis, all three TPCF tests were consistently less reactive than the TPI test.

3. In diseases other than syphilis, excluding the treponemal diseases yaws and pinta, the TPI test gave fewer reactions than the three TPCF procedures.

4. In the group of donors preselected by at least one nonreactive TPI test, approximately 5 percent (5 of 106) of the patients who were nonreactive with the TPI test in this study were reactive in the tpcf-50 test.

5. In the group of donors diagnosed as biological false-positive reactors by clinical impression and without previous screening with a TPI test, the reactivity rate was approximately the same with the tpcf-50 and TPI tests.

Research Support by Foundations and Health Agencies

During 1957, \$95 million was spent for scientific research and development by private philanthropic foundations and voluntary health agencies in the United States, the National Science Foundation reports. Of 4,067 private foundations surveyed, 438 reported research and development programs and a total outlay of \$72 million. Twenty-five of 30 voluntary health agencies reported expenditures of \$23 million.

Basic research received \$59 million of the total spent. Private foundations gave major support to the life sciences, about 45 percent of their total expenditures; social sciences were next in dollar support; physical sciences received the least. Almost one-half of the expenditures reported by the voluntary health agencies were to support biological and medical research.

Most of the expenditures were in the form of grants to outside organizations and individuals. Educational institutions and affiliated medical schools and hospitals were the major recipients.

These and other findings are a summary of preliminary data compiled for the National Science Foundation by the Bureau of Labor Statistics of the U.S. Department of Labor and published under the title "Research and Development Expenditures of Foundations and Health Agencies, 1957" as No. 15 of the Foundation's series "Reviews of Data on Research and Development."

Q fever in bovines, present in only 7 States in 1949, is now reported in 35 States. While the incidence of bovine infection appears to be increasing, the extent of transmission to man remains to be determined.

Report on the Nationwide Occurrence of Q Fever Infections in Cattle

LAURI LUOTO, D.V.M., M.P.H.

SINCE 1947, Q fever has been recognized as a public health problem in certain areas of the United States, particularly in the Western States. Special investigations have shown that human cases, some of which are severe and protracted, commonly occur in endemic areas in Texas, California, and Idaho. Recent reports (1) indicating that Q fever occurs in other States emphasize the need for further investigation of this infection of animals and man. A systematic study of the infection in livestock and of associated human disease is required to define the problem.

Dairy cattle, which are a major reservoir of infection and thus an abundant potential source of human disease, develop only asymptomatic infections. After the causative agent, *Coxiella burnetii*, is introduced into a herd, many animals develop chronic infections and transmit the agent to other additions to the herd; thus the herd usually remains permanently infected. Sheep and goats also are sources of the disease but are of lesser importance because their more limited distribution results in fewer human contacts. Although infection cycles may occur

among rodents and arthropods in nature, *C. burnetii* maintains an independent and more important airborne infection cycle among domestic livestock. This airborne transmission, along with the hardiness of the agent and its ability to persist in the environment, suggests a propensity for spreading and becoming a widespread public health problem.

Luoto (1) postulates that foci of Q fever occur and are spreading among dairy cattle in many areas of the United States and that the resulting gross environmental contamination will lead to frequent human infection and illness. In order to evaluate the public health significance of Q fever infections a three-phase study is planned: (a) the prevalence of the disease among dairy cattle will be determined by serologic surveys; (b) where foci of Q fever are found, surveys for human infection will be performed; and (c) the surveys will be followed, if indicated, by studies of the disease in man.

This is a report of findings dealing with the distribution, prevalence, and spread of Q fever among dairy cattle.

Dr. Luoto is senior veterinarian at the Rocky Mountain Laboratory, National Institute of Allergy and Infectious Diseases, Public Health Service. The laboratory is located in Hamilton, Mont. This is the third of a series of papers by Dr. Luoto on the epidemiology of Q fever in the United States.

Method of Study

Information on bovine infection was obtained by cooperative surveys in which State or local health and agricultural groups in 26 States participated. Herd milk specimens and serums ob-

tained by existing collecting agencies, such as mobile brucella test or milk control laboratories, were tested for antibody against *C. burnetii*. Tests of individual samples of milk or serums, isolation of the agent by guinea pig tests, and epizootiological studies were performed when indicated. Results were confirmed and correlated at the Rocky Mountain Laboratory, Hamilton, Mont.

The capillary-tube agglutination test (CAT) was used to detect antibody against *C. burnetii* in milk and various serums (2-4). This test, used in Q fever studies since 1952, has been evaluated by other groups (5,6) and found to be specific, sensitive, and reproducible. A close correlation exists between the presence of the agent in milk and of agglutinating antibody in milk or serum of individual animals.

Recent studies by Tjalma (7) and those to be reported by Luoto and Brock of tests performed during 1958-59 in Montana and Idaho indicate the reliability of the method for

testing pooled milk from entire herds; a positive result indicates the presence of one or more infected animals within the herd. Other studies by Krumbiegel in Wisconsin and Stoenner in Idaho during 1957-59 demonstrated that 79 to 84 percent of milk samples positive in the CA test yielded *C. burnetii* when inoculated into susceptible animals. The percentage of isolations increased directly with the titer of pooled milk, but the agent was not isolated from CAT-negative herd milk. While the exact sensitivity of this method for detecting infected animals within herds is uncertain, the test works effectively under field conditions. Infected herds and animals are being detected in areas where rates of infection among individual cows are only a fraction of 1 percent.

Distribution and Prevalence

Data now available demonstrate conclusively that Q fever occurs among dairy cattle in all parts of the United States. Bovine infections

Figure 1. The known distribution of naturally occurring Q fever infections in the United States

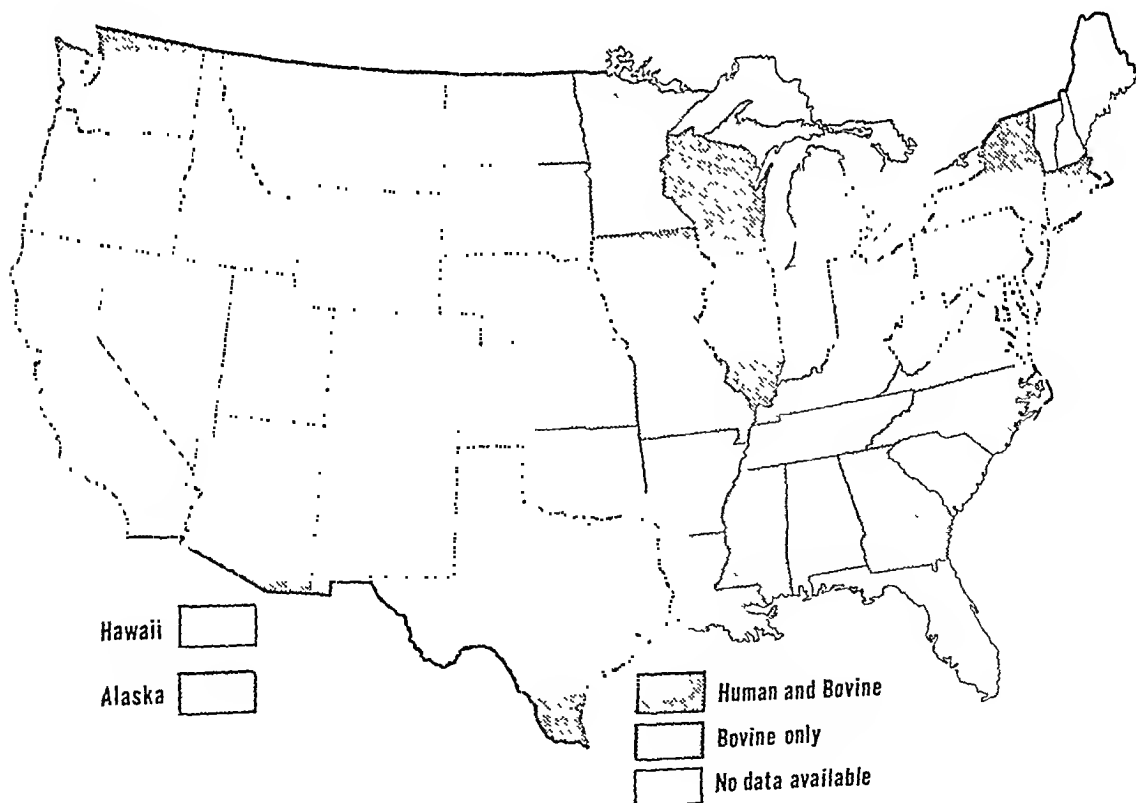

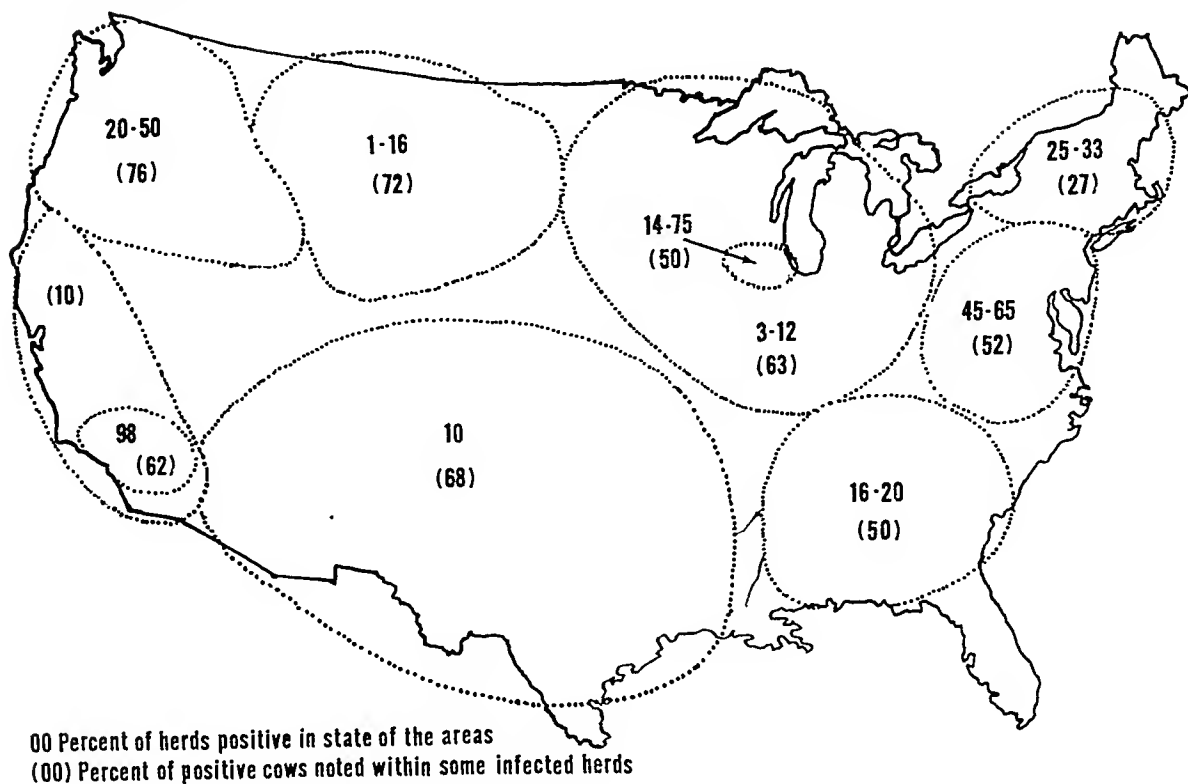

Figure 2. Prevalence of Q fever infection among dairy cows and herds in areas of the United States

have been demonstrated in 35 States (fig. 1) and have been found recently in all States where a concerted search has been made. Earlier studies indicated that bovine infections were frequent in seven States; namely, California, Wisconsin, Ohio, Iowa, Texas, Arizona, and Idaho (6-13). The current surveys in 26 States of 24,551 herds including 353,905 cows confirm and expand earlier findings in some areas and prove the occurrence of considerable bovine infection in 19 additional States—Oregon, Washington, Montana, Wyoming, Utah, South Dakota, Minnesota, Nebraska, Illinois, Michigan, Georgia, North Carolina, Maryland, Pennsylvania, New Jersey, New York, Connecticut, Massachusetts, and Hawaii. Other, more limited, data suggest that bovine infection occurs in nine other States; namely, Louisiana, Mississippi, Virginia (14), Colorado, New Mexico, North Dakota, Kansas, Missouri, and Kentucky (15). It is likely that infections occur in the remaining 15 unstudied States, most of which are adjacent to or surrounded by infected areas.

An unexpectedly high herd infection rate was encountered in most sections of the country, ranging from 1 to 65 percent within the various States (fig. 2). The finding of high levels of infection among dairy herds along the supposedly infection-free eastern seaboard is of special interest. Wide distribution of foci and variation in prevalence of infection was apparent. Within States having even the lowest rates, up to 14 percent of the herds in some areas were infected. Nearly 100 percent of the herds were infected in areas having more widespread infection. In Wisconsin, with a 7.7-percent herd infection rate, 75 percent of the herds were positive in some counties (9).

Not only were herd infections widespread, but a high percentage of infection occurred among animals within herds (fig. 2). Studies of several hundred cows within a dozen herds in each of several parts of the country revealed that over 50 percent of the animals within some herds are positive. Such levels of infection also exist among cows in focal areas where herd infections are infrequent. In Montana, with only

previously had no evidence of infection (15) but now have from 20 to 65 percent of the herds infected. A recent resurvey of a large Iowa milkshed by Tjalma showed a 100 percent increase in herd infections over that detected a year earlier (5); a similar increase is being observed by Krumbiegel among herds being resurveyed after 2 years in a Wisconsin milkshed.

Specific studies of the spread of infection among cattle, currently underway in Montana and Idaho, indicate that Q fever is spreading in these rural areas (table 2). Montana, which was considered previously to be free of bovine infection (3), now has infection in 1.2 percent of the 5,536 dairy herds tested. Infections increased from 2.2 to 4.3 percent, or from 19 to 34 herds among 852 herds resampled in 3 counties during a 5-month period of 1959 according to unpublished survey data. Within the same period, infections of individual cows increased from 9 to 17 among 32 animals in 2 herds observed. Similar studies by Brock in a heavily infected area of western Idaho show that during a 5-month period, herd infection more than doubled, from 42.3 to 90.1 percent, among 99 grade A herds resampled. The spread of herd infection was not uniform within the same or different areas.

Thus, infection has been shown to be spreading under rural conditions in at least 13 States, regardless of the prevalence of bovine Q fever. While the prevalence and rate of spread appear directly related to concentration of dairy cows, undoubtedly other unknown factors are involved.

Correlation With Human Infection

As could be expected, human infections occur and are diagnosed in areas where Q fever is known to exist in animal reservoirs. As the result of special interest and studies, Q fever is already recognized as a public health problem in some areas. At least 300 human cases were detected in southern California (17), and 350 cases were associated with sheep in northern California (18), during epidemiological studies in 1948-49. Additional cases are encountered annually. Cases originating from cattle or sheep have been recognized for many years in Texas and south central Idaho where epidemics

were studied in 1947 and in 1958 (19,13). Ten proven cases and evidence of infection in 85 individuals were found in Iowa by Tjalma where only 3 percent of dairy herds are infected. Human infection has been reported from 18 of the 35 States with known infected cows; an occasional human case is diagnosed in four "newly" infected States, namely, Maryland (20), Pennsylvania (21), New York, and New Jersey.

The true incidence of human infection, or of disease, within the United States is unknown because many cases are unrecognized. Even during the recognized epidemic in Idaho during 1958, most of the 93 laboratory-confirmed cases reported were diagnosed by about 10 percent of the local physicians, many of whom had diagnosed cases in previous years.

Significance of Findings

The demonstration of widespread bovine infection indicates that Q fever is endemic throughout the United States and that a nationwide problem already exists. The spread of infection even under dispersed rural conditions, as in Montana, sometimes occurs with rapidity and is a matter for concern. Universal bovine infection, similar to that in southern California where 98 percent of the herds are infected, may develop in other parts of the country. Such conditions are already approached in Western States, in Wisconsin, and in several Eastern States. The continuing growth of human and animal populations will result in crowding conditions even more conducive to spread of infection. Continued surveillance will indicate the development and scope of the animal disease problem.

In view of the widespread prevalence of bovine Q fever throughout the United States, information on associated human infections is urgently needed. Q fever is already a public health problem where the disease is endemic, with epidemic outbreaks, but the true magnitude of the problem in the United States remains to be determined. In many respects the failure to recognize Q fever in man is similar to the situation existing when brucellosis in man was first associated with a disease of cattle. From present knowledge concerning Q fever, it is difficult to conceive how infections

Table 1. Recent observations on the prevalence and spread of Q fever among dairy herds

1 percent of the herds infected, up to 72 percent of the cows within infected herds were positive.

These data on the distribution and prevalence of bovine infection have been extracted largely from reports of participating groups. Detailed reports on studies within individual States will appear elsewhere. In confirming the findings of various investigators, isolations of the agent were made from milks collected in 10 "newly" infected States. Current information indicates that *C. burnetii* is already well-seeded among dairy cattle in all parts of the country.

Spread of Infection Among Bovines

Reports in the literature suggest spread of infection among bovines in California, Wisconsin, Ohio, and Iowa (9,10,16). Recent unpublished observations on the prevalence of bovine infection constitute more conclusive evidence of

the spread of Q fever (table 1). These studies were done by CAT procedures while the earlier observations, except for the 364 herds from a mountain State, were based on guinea pig or complement fixation tests. The results are comparable, however, since the sensitivity of these test methods for detecting infections is quite similar (2, 3). These findings indicate that dairy herd infections in south central Idaho increased from 1 to 17 percent from 1951 to 1958 (13). A great increase occurred in an Eastern State where evidence of bovine infection was not detected in 1949, a little was present in 1952, but 47 percent of 248 herds tested were infected by 1959. Luoto and Stoenner have found that bovine infections increased appreciably in two mountain States between 1952 and 1958 (table 1). Other similar but perhaps less valid observations, because of inadequate baselines of infection, suggest that bovine Q fever is increasing in five Eastern States which

METROPOLITAN HOSPITAL PLANNING

CONFERENCE REPORT

HAS the time come for the Hill-Burton hospital and medical facility construction program to place more emphasis on the needs of the Nation's metropolitan centers?

This question was given serious consideration at a Conference of the Surgeon General with State and Territorial Hospital and Medical Facilities Survey and Construction Authorities held in Washington, March 9-11, 1959.

Hill-Burton State agency chiefs agreed that more attention should be directed to the growing dilemma facing metropolitan areas. The degree of emphasis, however, remained unsettled. General concepts evolved from the discussion were:

1. Urban hospital and medical facilities should be expanded in an orderly and coordinated manner.
2. Rural areas are not without medical facility problems, therefore continued attention should be given to their needs.
3. Geographic regions should be examined in order to view the problems of both metropolitan and rural areas in their proper perspective.

Prepared by John D. Theulis, chief of the Operations Branch, Division of Hospital and Medical Facilities, Public Health Service.

The conferees, in examining the problems of metropolitan hospitals, found that the chief complaint appeared to be insufficient funds for necessary construction. The complaint is chronic and widespread and extends even to hospitals in smaller communities. It is the result of many factors.

Many of our older hospitals were built without future needs in mind and grew as money became available to meet a recognized local need. Little or no thought was given to coordination of medical and hospital facilities to serve communities efficiently and economically. Many now obsolete hospitals, built 50 or more years ago, find that replacement would be more economical than modernization of the existing building.

Advances in medical science and technological progress have resulted in the need for new and costly equipment as well as changes in architectural design of facilities.

Socioeconomic, cultural, and demographic changes in our society have resulted in a shift of medical needs. The longer lifespan of the population and the growth of suburbs are among the many trends affecting medical needs unforeseen prior to the thirties when many metropolitan hospitals were built.

in man, perhaps even now occurring unrecognized, can fail to become even more widespread.

Regardless of any future implications, the presence of *C. burnetii*, a known pathogen, in animals and their products or environment presents situations which must be faced by responsible agricultural, industrial, and public health groups. Only through coordinated studies by many groups will data become available for evaluation of the problem. Public relations problems arise. Recognition and reporting of human infection should be promoted. Educational, diagnostic, and epidemiological services must be provided, along with possible regulatory and control measures.

Summary

Bovine Q fever must now be considered endemic throughout the United States, since infections are widespread and occur in all 35 States recently studied. Such infections are not only prevalent among cattle, sometimes to an alarming degree, but they are increasing and spreading even in rural areas. The spread of infection is expected to continue and may even accelerate in the future.

Human disease contracted from livestock is already a public health problem in some areas and is being recognized in others previously considered to be free of infection. Unrecognized human disease may occur in areas now known to contain endemic bovine infection.

Concerted nationwide studies of the occurrence and epidemiology of the disease are needed to define factors bearing on its occurrence and spread. Stimulation of the recognition and study of Q fever in man is necessary to ascertain the existence or possible development of a disease problem.

if urban hospitals are to maintain leadership in providing quality medical care, teaching, and research.

Gordon R. Cumming, of Berkeley, Calif., told the group that there is nothing "special" about metropolitan area planning. He suggested that "we must concentrate on the cities or the sub-orbits within them rather than plan grossly for a big group of 10 million people." He added that there is a surprising amount of useful information available about population trends, highway programs, and other such data needed in planning for the future. Referring to a study of the Los Angeles area, Cumming stated that "in tackling its planning, Los Angeles pegged the date 1975 toward which to build."

"As a second principle used in this study," Cumming stated, "we considered people and geography and distance and relationships, and evolved a concept of a central hospital service area and suburban areas, taking into account several characteristics. In each of the 14 hospital service areas, we defined the metropolitan community and where there should be a center with a community identity. Each of these areas have or will attain a population of at least 250,000 people by 1975.

"Third, we assumed the proposed traffic patterns for the future would persist. We'll still have traffic congestion in 1975, and we should plan for hospital services within about one-half hour's travel time. You can't travel very far even on a super-freeway in half an hour, if you count the time on a portal-to-portal basis.

"Finally, we asked what kind of institutions should serve these people and this geography? At first we thought of 200 beds as a minimum for a hospital, but upon the advice of people in the hospital field, this figure was reduced to 150."

The question of priorities (rural vs. metropolitan areas) was discussed by Dr. John R. McGibony, of Pittsburgh, Pa.

McGibony recalled that in the early days of the Hill-Burton program, considerable emphasis was placed on the needs of rural areas. He added that the time has now come "for us to direct more of our efforts toward meeting the needs of the urban, metropolitan areas."

In reviewing the approach taken in the theoretical blueprint of a coordinated system of hospitals, McGibony indicated there might have been more strength in such a system if the hub had been stronger. "The satellite facilities might have been stronger with a stronger central tie," he said.

McGibony noted that not enough emphasis has been placed on some factors in rising hospital costs. Referring to a recent article by Pat Groner, of Pensacola, Fla., he pointed out that the increase in use of existing X-ray facilities and laboratory services account for probably one-third of the increasing cost of hospital care, and that another one-third could be accounted for by other adjunct facilities and services.

"In meeting the demand," McGibony observed, "we tend to lose sight of the quality of care. If this is not a major item in planning, then most of the planning will go for naught, whether for diagnosis and therapy, prevention in both its primary and secondary aspects, or restoration or rehabilitation."

McGibony added that despite the fact that perhaps one-third of the internships and residencies in this country are served in non-primary university-connected hospitals, the urban metropolitan hospital complex is the seed of education for the health profession. Certainly a majority of the clinical and related research is in that setting, he said, and such education leads directly to the supply of personnel for satellite facilities.

On fund raising, McGibony said that industry will contribute as a general rule about 50 percent of the total capital outlay for an institution. He added that metropolitan, urban, and rural planning has to be a combined responsibility of all voluntary and governmental agencies.

"Hospital councils are meeting this need," he continued. "In Pittsburgh we have more than 60 hospitals working together closely in the improvement of care, services, and planning."

Ralph Murphy, of Baltimore, Md., placed special emphasis on the problem of obsolescence in metropolitan area hospitals. However, he said that there is much more to a

The conferees suggested that a major step toward aid to hospitals would be establishment of planning agencies on a permanent basis for each metropolitan area.

Remarks by George Bugbee, president of the Health Information Foundation of New York City, set the pattern for the panel discussion that followed. Other members of the panel, which was moderated by Dr. Robert N. Barr, secretary and executive officer of the Minnesota Department of Health, were: Gordon R. Cumming, chief of the bureau of hospitals, California State Department of Public Health; Dr. John R. McGibony, professor of hospital and medical administration, Graduate School of Public Health, University of Pittsburgh; Ralph Murphy, executive director of the Hospital Council of Baltimore, Md.; and Dr. Helen Knudsen, director of the hospital services division, Minnesota Department of Health.

Bugbee, who played an important role in the development of the Hill-Burton Hospital Survey and Construction Act, emphasized that the program provided an incentive for developing more adequate hospital and medical care in this country, adding:

"There has been general acknowledgment and approval of the act both in serving its purpose and in its administration. As with any national program, there is continued need for reevaluation of operating principles. Currently, there is considerable concern about whether the act and the priorities it established now permit the granting of funds for facilities where they are most needed in every State."

Referring to the need for replacement of older hospitals which have been leaders in quality in metropolitan centers, he said that several years ago the American Hospital Association estimated that such replacement would cost in excess of \$1 billion.

"Our oldest, largest, and finest general hospitals are located in cities," he said. "Evidence of the quality of patient care, teaching responsibilities, both graduate and postgraduate, and research, shows that these hospitals are our most important resources in maintaining and raising the quality of hospital and medical care nationwide."

While emphasis under the Hill-Burton pro-

gram has been directed to rural needs, a relatively large proportion of funds has gone to larger centers of population. This is supported by Bugbee's analysis of Hill-Burton grants from 1947 through the end of 1958. Grants during this period totaled \$1,091,801,000. He said that 45.7 percent of these funds was expended for all types of hospital and medical facilities in standard metropolitan areas where 56 percent of the Nation's total population lives. Central cities in these standard metropolitan areas which have 33 percent of our total population received 32 percent of the allocations. General hospitals have received 82 percent of all Hill-Burton funds, or a total of \$895 million since passage of the act; 43 percent of this amount was earmarked for standard metropolitan areas and 29 percent for central cities within these areas.

Explaining that he did not intend to evaluate urban needs with a view toward shifting priorities, Bugbee pointed out that only with adequate planning can priorities be applied intelligently. There is currently a great upsurge in demands for better metropolitan planning, he emphasized.

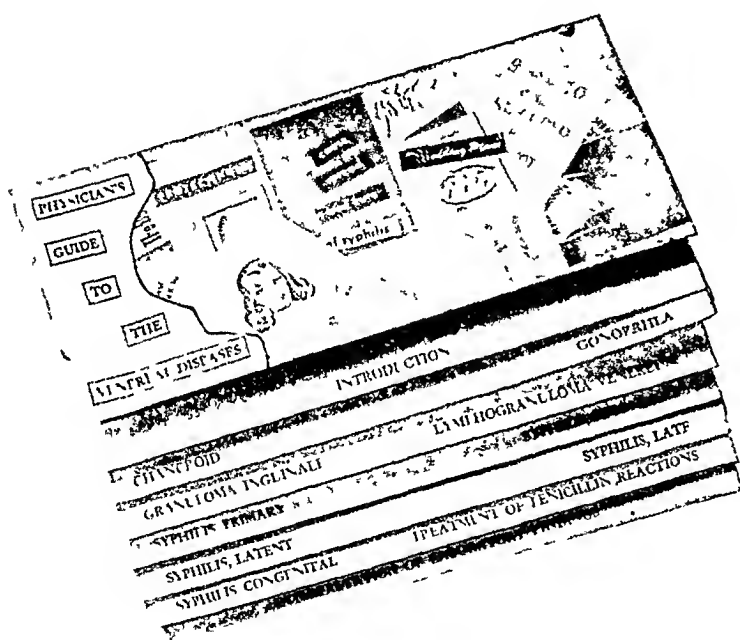

Suburban growth was cited by Bugbee as a big complication. He noted that population shifts to the suburbs have changed the texture of the central city population and its ability to finance hospital care, resources available for capital fund raising, and distribution of physicians.

A community planning agency should be independent of other community organizations, Bugbee suggested. He explained that "The agency must be representative of the community. Its active members, particularly, should be selected for their objectivity, community-mindedness, and, in the instances that apply, for their sense of responsibility in raising funds. It would be desirable if the agency would be designated by the State planning agency as its affiliate organization in the metropolitan center. Planning is not a temporary function—the agency must be set up on a relatively permanent basis."

Another point emphasized is the need for further research to aid in establishing more definitive goals. This, Bugbee said, is essential

the detriment of rural areas, the conferees agreed that planning is just as important in the large communities as it is in the smaller communities and the problems are just as great in one area as in the other. It was emphasized that one of the greatest strengths of the Hill-Burton program has been central planning for the whole State. Further, that, while the needs of metropolitan areas could be emphasized more and more in future planning, this need

probably should be developed jointly by local planning groups with participation and direction on the part of the State Hill-Burton agency. Experience indicates that no one area of a State can and should plan independently of other areas. The conferees agreed that the success of the Hill-Burton program justified the role of a statewide planning agency in any future efforts to meet the hospital and medical facility needs of all segments of the population.

HEALTH
EDUCATION
CASE
HISTORY

lymphogranuloma venereum, syphilis (primary, secondary, latent, late, congenital), treatment of penicillin reactions, and interpretation of laboratory findings. The subjects are printed on the projecting margin of the page (see illustration).

The brochure, in addition to explaining diagnostic and therapeutic processes, points out the necessity of joint responsibility of the private physician and the public health department in the control of these diseases and discusses the services and facilities of the department that are available to the private practitioner. The pamphlet was presented in connection with a seminar held in Washington in October 1959 in cooperation with the Public Health Service. It is being distributed on a continuing basis to all physicians in private practice in the District.

Guide to Venereal Diseases

An unusually well-designed information piece, *A Physician's Guide to the Venereal Diseases*, has been printed by the preventable and chronic diseases division of the District of Columbia Department of Public Health, which gives its ad-

dress and telephone number, with the date of publication on the back. The pages are folded horizontally so that each one successively projects enough to provide a ready index to the subjects treated: chaneroid, gonorrhea, granuloma inguinale,

hospital than the excellence of its physical facilities. "While physical facilities are important in a very real sense," he said, "the excellence of a hospital depends upon the people and staff." As an example, he stated that patients in pre-1900 beds do not necessarily receive poorer care than those in newer beds.

Murphy added that one of the major needs in metropolitan planning is to deal realistically with the problem of obsolescence. Furthermore, it is necessary to face up to the economics of the problem—especially as it relates to replacement versus modernization. This requires the development of measures of obsolescence which are realistic and meaningful to both the community and the hospital involved. Murphy explained that the position taken by the individual hospital regarding obsolescence is usually based upon its own situation and does not always correspond to the community viewpoint.

Murphy said it is agreed that the ring of very small hospitals in the suburbs is to be avoided. However, people are not reassured by statistics indicating that less than 1 percent requires a hospital within the first 10 minutes after an emergency. Therefore, suburban hospitals which are desirably sized and staffed are a vital component of the overall plan for adequate hospital service in a metropolitan area.

Agreeing with the need for additional research, Murphy pointed out that current planning must be based on the knowledge we have. He observed that frequently maximum use is not made of the vast amount of data already gathered.

Added to the obstacles facing hospital planners are the unpredictable and intangible factors which should be considered. An example is estimates of population growth. The erroneous predictions made by the demographers in the thirties could easily be repeated.

Two conclusions, based on the fact that hospital planning still is an inexact science, were drawn by Murphy. First, he said, planning must be flexible. Second, plans should be based on the needs and past experience of an individual community. He warned against the inadvisability of one community adopting plans which were devised to meet the needs of a different type of community.

Dr. Helen Knudsen, of Minneapolis, Minn., told of problems encountered in two metropolitan areas, Minneapolis and St. Paul, existing side by side, but operating independently. She said that assistance had been given Minneapolis in surveying needs as preparation for a united hospital fund raising drive. On the other hand, St. Paul does not have a planning group, each hospital raising its own funds.

"We're very concerned in our office," Knudsen said. "We have attempted for some time to persuade St. Paul authorities to organize an overall planning group."

The difficulties of hospital planners are not confined to metropolitan areas, Knudsen said, citing the real problem in rural development. She noted that at one time or another, practically every town in Minnesota has discussed construction of a community hospital, whether it needed a hospital or not. "I'm sure we can say that we spend as much time trying to discourage some of these smaller communities from building as we do trying to encourage others to plan and raise funds," she said.

However, after the would-be sponsors of a community hospital are convinced that it is not justified, they become very realistic and grateful for the advice, she added. Instead of building a hospital, the sponsors may build a clinic more suited to their needs.

"The Minnesota State Board of Health has now adopted a policy requiring every applicant to submit a realistic plan for staffing before Hill-Burton money will be allocated," Knudsen said.

During the general discussion, attention was again given to the question of emphasis in the Hill-Burton program. Reference was made to the statistics cited by Bugbee that since 29 percent of Hill-Burton funds were allocated to central cities where 33 percent of the population lives, the needs of our large areas have not been disregarded "by any manner of means."

It was emphasized that much credit is due to State agencies for planning their programs in such a way that, while taking care of the peripheral needs, and the needs of rural areas, a good job has been done in the central cities.

While they cautioned that attention should not be directed to the needs of urban areas to

Table 3. Strontium 90 content of fresh vegetable samples, by State, 1958-59¹

³ Not available.

tables so far analyzed for this nuclide ranged from 0.5 micromicrocurie per kilogram for potatoes from California to 16.8 for lettuce also grown in California (table 3). Other States covered in the strontium 90 analyses so far completed include Maryland, Kansas, Ohio, Texas, Minnesota, and Illinois.

The National Committee on Radiation Protection and Measurements has recommended 80 micromicrocuries of strontium 90 per liter of liquid or kilogram of solid food as the maximum permissible level, for human consumption, in the diet over an entire lifetime. These levels may be exceeded by varying amounts for varying periods without causing appreciable harm to the individual.

The Food and Drug Administration pointed out that an additional safety factor is provided by the washing, peeling, and trimming which is a normal part of preparation of vegetables either by the housewife or by the commercial processing plant. However, it is not yet known whether some vegetables have a greater affinity for strontium 90 than others.

Total radioactivity and strontium 90 contents of vegetables examined to date are far below the results reported in August 1959 for

alfalfa hay. Average total radioactivity for the hay samples was 27,200 micromicrocuries per kilogram, and strontium 90 content ranged as high as 804 micromicrocuries per kilogram.

Alfalfa hay, however, is primarily animal feed rather than human food and the amount of strontium 90 appearing in milk is considerably less than the amount in the cow's diet.

Of the 14 States from which alfalfa hay was sampled, 13 were included in the vegetable samplings. There was considerable overlapping in the time intervals covered by the samplings. The alfalfa samples in every instance showed significantly higher radioactivity on the average than the vegetable samples from the same States. Ensilage samples were found to contain less total radioactivity than alfalfa hay, but in most instances more than the vegetables from the same State.

Reasons for the differences observed between alfalfa hay, ensilage, and vegetables are not as yet known, but presumably may include such variables as moisture content of the crop, length of growing season, climatic factors, and differences in plant metabolism.

In the Food and Drug Administration survey of human food and animal feeds, the beta

Radioactivity in Fresh Vegetables

THE Food and Drug Administration's second report on radioactivity in fresh vegetables finds the amount still well within limits recommended by the National Committee on Radiation Protection and Measurements. The report covered 402 samples collected in the latter half of 1958 and 139 collected in 1959. Specimens included cabbage, cauliflower, celery, beans, broccoli, brussels sprouts, collards, beet tops, lettuce, kale, mustard greens, parsley, potatoes, tomatoes, peppers, spinach, turnip greens, and watercress (table 1).

The highest average total beta radioactivity found for any vegetable so far examined was 6,700 micromicrocuries per kilogram of a sample of spinach. The average for all vegetable samples from all sources was 2,520 micromicrocuries per kilogram. The highest single value of total radioactivity was 56,000 micro-

microcuries per kilogram obtained on a sample of spinach from Illinois (table 2). (One micromicrocurie is a radioactivity of an average of 2.2 disintegrations per minute.)

Samples of certain U.S. staple foods are sent by the Food and Drug Administration to the Lamont Geological Observatory for strontium 90 analysis. Strontium 90 contents of vege-

Morbidity and Mortality Characteristics of Asian Strain Influenza

TOM D. Y. CHIN, M.D., M.P.H., JOHN F. FOLEY, M.D., IRENE L. DOTO, M.A.,
CLIFTON R. GRAVELLE, M.S., and JEAN WESTON, A.B.

DURING the fall of 1957 acute respiratory disease occurred in epidemic prevalence in the greater Kansas City area. The clinical and epidemiological picture of illnesses was typical of influenza. The majority were influenza-like, characterized by a sudden onset of fever, headache, malaise, sore throat, coryza, cough, and muscular aching. The outbreak was explosive, disseminated rapidly through the population, and caused high attack rates among persons of all ages. The number of deaths, particularly deaths attributed to pneumonia, increased.

The outbreak was first noted in September 1957 in the southwest section of Kansas City, Mo., where an abrupt rise in absenteeism from respiratory disease was reported from Southwest High School. The disease then appeared in other high schools in the city. The daily rate of absenteeism reported from five high schools during the epidemic period varied from 11 to 38 percent. The usual daily absenteeism had been less than 5 percent. Approximately 4 weeks following the high school outbreaks, a

marked rise in absenteeism was reported in the grammar schools. Inquiries made of four elementary schools on October 15 indicated rates of absenteeism ranging from 33 to 67 percent. There was an abnormal incidence of respiratory infections among workers in various industries in Kansas City, with the peak incidence occurring during the middle of October.

Most of the influenza-like illnesses observed during the epidemic period were probably Asian influenza. This assumption was reflected by the results of etiological studies performed on throat washings (or swabs) and on acute and convalescent serums obtained from several groups of patients with influenza-like illnesses. The specimens came from four principal sources: high school students, student nurses seen at the student health service of the University of Kansas Medical Center, patients seen in offices of private physicians, and patients in various Kansas City hospitals.

An influenza virus which was antigenically related to the Asian strain (A2/Japan/305/57) was recovered from 41 of 75 patients (55 percent) by inoculation of throat washings into the amniotic cavity of 12-day-old embryonated eggs. Acute and convalescent serum samples from 18 of 32 patients showed a fourfold or greater rise in hemagglutination-inhibition antibody titers, with the A2/Japan/305/57 strain of virus used as the antigen. Thirty of the 75 patients from whom throat washings were obtained were seen at the student health service where a separate study on influenza was conducted. Twenty-two of them (73 percent) with illnesses diagnosed clinically as influenza

Dr. Chin is assistant chief, Dr. Foley, an epidemic intelligence officer, Miss Doto, statistician, and Mr. Gravelle, virologist, of the Kansas City Field Station, Communicable Disease Center, Public Health Service. Mrs. Weston is research assistant, section for virus research, department of pediatrics, University of Kansas School of Medicine, Kansas City, Kans.

This study was supported in part by a grant from the Common Cold Foundation to the University of Kansas School of Medicine.

particles are detected by an instrument which determines the presence of beta radioactivity from all elements, including those which occur in fallout, as well as those in nature, such as potassium 40.

In order to measure beta radioactivity values that relate to fallout only, allowance must be made for this ubiquitous species of potassium. All total beta radioactivity values reported in the survey have therefore been adjusted by subtracting an amount attributed to potassium 40.

The significance of a total beta radioactivity value is determined by the age of the sample. A sample may be extremely radioactive immediately after exposure to fresh products of a fission reaction, but within a few days it will lose that proportion of radioactivity produced by short-lived nuclides. With time, the proportion of beta radioactivity due to strontium 90 and cesium 137 increases, while total radioactivity declines. Half the radioactivity of strontium 90 and cesium 137 is discharged in about 30 years.

WHO Fellowships for Foreign Study

At the request of the United States Government, the World Health Organization has provided a limited number of short-term fellowships in 1960 for the "improvement and expansion of health services."

The World Health Organization Fellowship Selection Committee, recently established by Surgeon General Leroy E. Burney, is chaired by Assistant Surgeon General David E. Price. Dr. John Parks, Dr. Fred L. Soper, and Miss Julia Thompson, represent the Association of American Medical Colleges, The American Public Health Association, and the American Nurses Association on the committee.

Applications for fellowships in various branches of public health and allied fields will be considered. Applicants must be engaged in full-time public health or educational work. In making selections, the committee will consider the ability of the individual and the importance of the contribution which his foreign study will make on his return.

Fellowships will pay per diem and transportation and, except in very unusual circumstances, will cover from 2 to 6 months. Employers will be expected to endorse applications and to continue salary payments for the duration of fellowships.

The deadline for the receipt of applications has been extended to March 15, 1960. Further information and application forms may be obtained from Dr. Howard M. Kline, Secretary, World Health Organization Fellowship Selection Committee, Public Health Service, Washington 25, D.C.

Figure 1. Incidence of influenza-like illness by date of onset in 745 students of Southwest High School, Kansas City, Mo., 1957

1,927 persons reporting having had an influenza-like illness, 84 percent had fever; 73 percent, headache; 77 percent, cough; 63 percent, sore throat; and 61 percent, coryza. A history of chest pain was given by 23 percent. A majority of the illnesses lasted 3-7 days.

The incidence of influenza-like illness (745 cases with date of onset given) reported among the high school students according to date of onset is depicted in figure 1. During August and the first few days of September, there were only sporadic cases. On September 6, the number of cases increased suddenly. The high attack rates were sustained for the next 2 weeks, and then abruptly declined. Although abnormal incidence continued for 3 additional weeks, the number of cases reported were of a much lower order of magnitude.

The epidemic curve describing the occurrence of 776 cases among the family contacts for which a date of onset was given (fig. 2) is similar to that of the high school students except that the ascending limb was less abrupt and the

peak of the curve was broader. While the incidence in the high school had fallen precipitously by September 21, incidence continued to be high among the family contacts and was sustained until October 20, after which it abruptly declined.

Thirty-four percent of the 5,822 persons had influenza-like illnesses. The highest attack rate, slightly more than 50 percent, was observed in children aged 10-19 years (table 1 and fig. 3). Among children under 10 years of age, about one-third experienced clinical infection. About 27 percent of the young adults gave a history of having had an influenza-like illness, while in persons 40 years and older the incidence was 17 percent. There was no significant difference in the sex distribution.

The age-specific attack rates among the students attending Southwest High School were relatively uniform, ranging from 50 to 69 percent. The overall attack rate in this group was 59 percent.

The incidence of influenza-like illnesses

were shown to have had Asian influenza (T. D. Y. Chin and R. A. Jordan, unpublished data).

In addition, lung tissue specimens were obtained at autopsy from 11 patients who had pneumonia. The Asian strain of influenza virus was recovered from eight patients by inoculation of tissue suspension intra-amniotically into embryonated eggs.

The data presented in this report describe the morbidity and mortality observations made during the epidemic. The morbidity study was made on a group of high school students and their families. The mortality observations were limited to the influenza and pneumonia deaths reported in Kansas City, Mo. The data describing the efficacy of immunization with monovalent vaccine (A2/Japan/305/57) in prevention of influenza-like illness have been reported in a separate publication (1).

Methods of Study

The morbidity studies were carried out on a group of students of Southwest High School and their families. The school is located in an upper middle-class residential neighborhood in the southwest section of Kansas City. It had an enrollment of 2,123 students attending grades 8-12. Morbidity data were obtained from a questionnaire which was designed to determine the extent of the epidemic in the school and the epidemiological characteristics of influenza occurring in the students and all members of their families. The questionnaire requested the usual identifying data, a family roster, names of the school children were attending, occurrence of influenza-like illness since August 15, 1957, date of onset and duration of illness, a checklist of symptoms referable to the respiratory system, and a history of vaccination against influenza.

Each student was given a questionnaire to be completed by or under supervision of a parent, and was instructed to return only one completed form per family. The questionnaires were distributed by classroom teachers on October 22, about 1 month after the peak of the epidemic in the school; the completed questionnaires were returned on October 24.

A few families indicated in the questionnaires

that influenza-like illness had occurred during the last week of July and the first part of August. Therefore, the rates presented in this paper were based on the influenza-like illnesses reported between July 25 and October 24.

A total of 1,429 forms were returned. After eliminating 45 inadequate or incomplete forms and 29 duplications, the forms completed by 1,355 families formed the basis for the report. The total population was 5,822 persons (an average of 4.3 per family), including 1,577 members (74 percent) of the student body. No information was available about the characteristics of the remaining 26 percent of the students and their families.

The mortality studies were limited to the reported influenza and pneumonia deaths of residents of Kansas City, Mo., from October 1, 1957, to March 31, 1958. A plan to obtain epidemiological data was organized during the first week of October when a sudden rise in the number of pneumonia deaths was noted. Each week a list of deaths attributed to influenza and pneumonia was obtained from the Kansas City (Mo.) Health Department. For each case epidemiological data were obtained about age, sex, and associations with influenza and with known chronic disease or other conditions, such as pregnancy and postoperative complications. Sources of this information were hospital records and interviews with physicians, relatives, or friends of the deceased. Whenever possible autopsy material consisting of samples of trachea or lung was obtained for virus isolations.

In this study a death was considered related to influenza when one of the following criteria was met: (a) symptoms of influenza were present, (b) influenza-like illness was present concurrently or within 1 week from date of onset of illness in one or more familial associates of the deceased patient, or (c) the Asian strain of influenza virus was recovered from post-mortem tissue specimens.

Morbidity Among Students and Families

The general clinical picture of the illnesses of the students and their families consisted of fever of 100° to 104° F., chills, headache, sore throat, malaise, cough, and coryza. Of the

Figure 1. Incidence of influenza-like illness by date of onset in 745 students of Southwest High School, Kansas City, Mo., 1957

1,927 persons reporting having had an influenza-like illness, 84 percent had fever; 73 percent, headache; 77 percent, cough; 63 percent, sore throat; and 61 percent, coryza. A history of chest pain was given by 23 percent. A majority of the illnesses lasted 3-7 days.

The incidence of influenza-like illness (745 cases with date of onset given) reported among the high school students according to date of onset is depicted in figure 1. During August and the first few days of September, there were only sporadic cases. On September 6, the number of cases increased suddenly. The high attack rates were sustained for the next 2 weeks, and then abruptly declined. Although abnormal incidence continued for 3 additional weeks, the number of cases reported were of a much lower order of magnitude.

The epidemic curve describing the occurrence of 776 cases among the family contacts for which a date of onset was given (fig. 2) is similar to that of the high school students except that the ascending limb was less abrupt and the

peak of the curve was broader. While the incidence in the high school had fallen precipitously by September 21, incidence continued to be high among the family contacts and was sustained until October 20, after which it abruptly declined.

Thirty-four percent of the 5,822 persons had influenza-like illnesses. The highest attack rate, slightly more than 50 percent, was observed in children aged 10-19 years (table 1 and fig. 3). Among children under 10 years of age, about one-third experienced clinical infection. About 27 percent of the young adults gave a history of having had an influenza-like illness, while in persons 40 years and older the incidence was 17 percent. There was no significant difference in the sex distribution.

The age-specific attack rates among the students attending Southwest High School were relatively uniform, ranging from 50 to 69 percent. The overall attack rate in this group was 59 percent.

The incidence of influenza-like illnesses

Figure 2. Incidence of influenza-like illness by date of onset in 776 family contacts of Southwest High School students, Kansas City, Mo., 1957

among the family contacts of the students of Southwest High School is summarized in table 2. The overall attack rate was 24 percent. The attack rates among children under 20 years of age were relatively uniform, ranging from 32 to 39 percent and decreasing with age. The rates among the teenage family contacts were considerably lower than those observed in the high school students.

The attack rates with respect to family size are shown in table 3. Of 1,303 families included in this analysis, 85 percent were families with three to five members; the remaining 15 percent had six or more persons per family. The attack rate in three-member households was 30.7 percent; the incidence then gradually increased with family size to 40.5 percent in households having seven or more members per family.

The mean secondary attack rate was 14 percent. This observation was based on 2,596 persons exposed to index cases (first clinical case occurring in a family) in 712 families. The incidence of secondary cases with respect to age is shown in table 4. In calculating these rates, persons who became ill 1-10 days following ex-

posure to index cases were considered secondary cases. As expected, the rates among children were higher than those of adults, with the highest incidence in children aged 10-19 years. The secondary attack rate among children in the age group 10-19 years was slightly higher than that observed in children under 9 years of age; the difference, however, was probably not real, as it could have occurred by chance about 2 out of 10 times ($P=0.23$). The rates among adults in the age groups 20 years and older were substantially lower.

When the distribution of 729 index cases (including 17 co-primary cases) by age was examined, 586 (80 percent) were found to be persons between 10 and 19 years of age. All but nine of these were students attending Southwest High School. As expected, less than 1 percent of the index cases were in children under 5 years. Frequency in age groups 20 years and over ranged from 2 to 4 percent. If index cases were presumed to carry the infection into the household, it appears that in this outbreak the high school students were the most frequent sources of household infections. Unfortu-

Figure 3. Incidence of influenza-like illness by age and sex among 1,355 families, Kansas City, Mo., July 25–October 24, 1957

nately, similar studies were not carried out in an elementary or a junior high school to determine similar relationship.

Influenza and Pneumonia Mortality

The total number of deaths from influenza and pneumonia reported among residents of

Kansas City, Mo., from October 1, 1957, to March 31, 1958, was 253, a mortality rate of 49.6 per 100,000 population for the 6-month period. This incidence is compared with that reported for the same period in each of 5 preceding years (table 5). The rate for the fall and winter, 1952–53, was 35.2, about one-third less than that

Table 1. Incidence of influenza-like illness by age and sex among 1,355 families, Southwest High School, Kansas City, Mo., July 25–October 24, 1957

reported during the 1957–58 epidemic. In the winter of 1952–53 influenza A' infections were prevalent in the United States and were known to cause localized outbreaks in Missouri (2). During the 4 noninfluenza years, the mortality rates were one-half to one-third as high as those observed during the 1957–58 epidemic.

From October 1957 to March 1958, 7.4 per cent of the deaths were attributed to pneumonia and influenza. This figure is significantly higher than that reported for each of the 5 preceding years (table 6). The number of deaths from causes other than pneumonia and influenza was also higher during the 1957–58

epidemic as compared with that of the 4 non-influenza years.

The number of influenza and pneumonia deaths reported weekly for 1957–58 was compared with the adjusted average for the period 1952–57 (fig. 4). Two distinct waves of excess mortality were observed during the 1957–58 epidemic, one occurring in October and November and the other in the latter part of February. The 1952–57 curve does not show similar rises although the number of deaths increased slightly late in December and in the month of January; the slight increase undoubtedly represents a normal seasonal variation in deaths from acute respiratory disease.

The age-specific mortality rates based on 253 influenza and pneumonia deaths are shown in table 7. The highest rates were observed in the very young and the very old. The rate among children under 1 year was 529 per 100,000 population. In persons 65 years and older the range was from 185 to 521 per 100,000, with the rates rising as age increased. The age-specific death rates for 1957–58 were generally higher than those for the same period in the preceding 5 years. These differences were particularly noticeable in persons under 1 year of age and in the older age groups.

Although the age-specific death rates of the 1957–58 epidemic were higher in certain age groups, the age pattern of influenza and pneu-

1957-58.....	253	49.6

¹ Based on population estimates, City Health Department, Kansas City, Mo.

monia deaths was essentially unaltered. The age distribution observed in the 1957 epidemic was almost identical to that of the preceding 5 years (fig. 5).

The number of male deaths was significantly higher than female, 147 compared with 106. The probability of this difference occurring by chance is 1 in 100 when the proportion of males to females in the population is assumed to be equal.

Of the 253 influenza and pneumonia deaths, an adequate clinical history was obtained concerning 237. According to the criteria previously defined, 100 of the 237 deaths (42 percent) were associated with influenza; 80 patients had a history of influenza or an influenza-like illness, and 20 did not have symptoms of influenza but influenza-like illnesses were reported among the familial associates. Of the remaining 137 persons, history of influenza was not elicited as a part of the clinical picture nor was influenza observed among their familial associates.

Discussion

Three main criticisms are immediately evident in this study: (a) the questionnaire method of data collection is not as accurate nor as uniform as data obtained by an experienced medi-

cal interviewer, (b) the population selected was limited to families with children of high school age, and (c) virologic studies were performed on a relatively small sample of cases. Despite these weaknesses, the clinical and epidemiological data derived clearly indicate that the epidemic was influenza and a majority of the illnesses observed during September and October were probably caused by the Asian strain of influenza virus.

The case incidence was high, reflecting the infectiousness of the agent invading a highly susceptible population. The overall morbidity rate of the survey population was 34 percent. The rate among the students attending Southwest High School was considerably higher, however, than that of the teenage household contacts not attending the same school. This observation indicates that the outbreak was cen-

tered in the high school and the infection spread to family contacts. This manner of spread undoubtedly explains the high frequency of index cases observed among the Southwest High School students.

The variations in age-specific incidence are worthy of note. Although the Asian strain showed a marked difference in its antigenic property from all previously known strains of influenza virus and only a small fraction of the older population was shown to possess strain-specific antibody (34), not all persons were equally susceptible to the disease. The age distribution curve indicates that susceptibility to Asian influenza was greatest among teenagers, with progressive reduction as age increased. This type of age pattern was also reported in studies of Asian influenza in Louisiana (5) and in Melbourne, Australia (6).

Figure 4. Deaths associated with influenza and pneumonia by week,¹ Kansas City, Mo., October-March, 1957-58 and 1952-57

¹The method of adjustment used to obtain the weekly average for 1952-57 is that described in the 1957 Morbidity and Mortality Weekly Reports published by the National Office of Vital Statistics, Public Health Service.

Figure 5. Percent distribution by age of influenza and pneumonia deaths, Kansas City, Mo., October–March, 1957–58 and 1953–57

The high attack rate observed among teenagers can be partially explained by the increased risk of exposure, since the epidemic was centered in the high school where more than half of the student body had experienced clinical influenza. The progressive decline in the incidence with increasing age probably is a reflection of partial immunity which was presumably acquired as a result of repeated infections with the influenza virus in the past. Evidence in support of this explanation has been suggested by the work of Francis and associates (7, 8) who demonstrated a high degree of correlation between progressive increase in resistance to influenza and acquisition with age of broader antibody spectrum because of repeated experiences with many antigenic variants of influenza virus. The recent study of Hilleman and associates (4) also lends support to this thesis.

Although the attack rate was higher in children aged 10–19 years than in those aged 0–9 years, such age selection was not evident among the family contacts. However, these results

are to be expected when children are exposed in a household environment where the degree of exposure becomes more equal. This observation seems to further support the premise that the increased attack rate which occurred among the teenagers was due to the greater risk of exposure in the school.

Two distinct peaks were clearly evident in the mortality curve, one occurring in the fall of 1957 and the other in February 1958. This pattern is similar to that observed elsewhere in the United States (9). The first wave of excess mortality was coincident with the sharp outbreak of influenza which occurred during the fall. The second, lesser wave of mortality also occurred during a period of increased prevalence of influenza. Infections in the second period were widely scattered and were limited to single families or small groups of persons such as those in hospital wards or in nursing homes. No survey was made to ascertain the extent of influenza occurring in the community at that time. However, examination of the admission records for respiratory disease at the

student health service of the University of Kansas Medical Center clearly indicates that a lesser, second wave of acute respiratory infections occurred in the month of February and the first part of March. Seventeen (90 percent) of 19 patients studied during this secondary wave were etiologically proved to have had Asian influenza (T. D. Y. Chin and R. A. Jordan, unpublished data).

While the number of pneumonia deaths observed in the current epidemic was significantly higher than that reported for the nonepidemic periods, the age pattern of the deaths was essentially unaltered. The skewed U-shaped curve was similar to that seen in Asian influenza outbreaks occurring elsewhere (10,11). There was no indication, however, that it had any resemblance to the pattern of the 1918 experience, when nearly 50 percent of the deaths from influenza and pneumonia were of persons aged 20-40 years (12).

Summary

Asian influenza appeared in epidemic prevalence in the greater Kansas City area during the fall of 1957, followed by a minor secondary wave during the winter of 1958. A survey of 5,822 persons during the fall epidemic revealed an attack rate of 34 percent. The highest attack rate was observed in persons aged 10-19 years, with a decline in rates with increasing age.

The rate of clinical infection was related to family size, varying from 30.7 percent in three-member households to 40.5 percent in households with seven or more members. The secondary attack rate was 14 percent.

A total of 253 deaths due to influenza and pneumonia was reported in Kansas City, Mo., from October 1, 1957, to March 31, 1958, a mortality rate of 49.6 per 100,000. This rate was two to three times higher than that of the 4 preceding noninfluenza years.

Two peaks were observed in the mortality curve, one occurring in October and November, and the secondary peak in the latter part of February. The highest death rates were observed in the very young and the very old.

Seventy-three percent of the persons who died had a history of pre-existing chronic disease or other associated conditions, the majority of which were listed as cardiovascular or chronic pulmonary disease.

Evaluation of Food Sanitation Programs

F. GLENN LYNCH, M.P.H.

THE EVALUATION of programs in many public health endeavors has aroused increasing discussion and interest in recent years. The concepts applied to the evaluation of the restaurant sanitation program of a local health department could, with slight modification, be adapted to a number of other programs.

At least two methods of evaluation must be considered before the equation, input equals output, comes near to being balanced.

In restaurant sanitation programs a realistic objective must be developed and work directed toward that end. When this objective has reasonably been reached, it must be maintained as long as it has public health meaning. Going through the motions of inspecting restaurants year after year with no realistic objectives is not only wasteful but nonprofessional. When a public health program or procedure becomes traditional and has lost its public health significance, it is past time for a thorough reappraisal. New objectives and new methods of accomplishing these objectives must be set forth.

The first method of evaluation, which will be merely mentioned, is cost versus value received. Restaurant sanitation programs cost dollars. Health officers, sanitarians, and others interested in fiscal management must eventually place a value in dollars not only on restaurant sanitation programs but on many other public health services. Programs may be altered and adjusted so that maximum value and acceptable standards can be achieved with a minimum of expenditure.

Mr. Lynch is chief of environmental sanitation, Berkeley (Calif.) Department of Public Health. The article is based on a paper given at the meeting of the Western Branch of the American Public Health Association, in San Francisco, June 1959.

The second method of evaluation is to devise a means of measuring programs or achievements. Not many years ago, restaurant sanitation programs were loosely organized with little if any system and no professional objective. In general, the policy was to inspect restaurants when there was time and then try to get the owners to comply with the law.

If restaurant sanitation is to be approached in a professional manner, the sanitarian must not visit a restaurant, tell the proprietor that this or that needs correction, and walk out, only to return at some undetermined future date and, parrotlike, go through the same motions again.

In all scientific approaches the coarser measurements are made first. Most sanitarians have measured restaurant sanitation activities; for example, number of inspections, rechecks, and visits. These measurements are crude and perhaps served a purpose in years past, but do they really tell anything? In a certain district there were 46 restaurant inspections during the month. The exact number of restaurant inspections made in a specific district is meaningless unless the only purpose is to justify the time devoted to them. The time spent and the number of restaurants visited must somehow be related to accomplishment if this number is to have any meaning. If a sanitarian were to list his accomplishments during 1 month, it would have more significance.

There are two methods for establishing a baseline for a program and making subsequent measurements of progress. The first is a professional evaluation by an outside source, using a standardized scoring system, and the second is a self-appraisal based on the same standardized method.

An appraisal by an outside agency may be opposed by a few who have something to hide,

but more probably would be opposed by those who feel insecure about their activities. Such verbal reactions to an outside appraisal as, "My sanitarians and I know just as much about restaurant sanitation as they do," and "We don't need anyone to tell us anything," reflect a defensive attitude of sanitarians and directors of sanitation. They feel their competence and integrity are being threatened.

Their nonverbal thinking might be expressed as: "I am really afraid they will find the situation is not very good." "Maybe they will comment to the health officer that I am not doing a good job." "Perhaps State funds will be held back because of a substandard program." "Information may be given to the newspapers."

Attorneys, engineers, and physicians often call on consultants for advice and assistance without loss of professional integrity. Sanitarians can also do so in order to utilize collective knowledge to do the best possible work for their community.

Many sanitarians find restaurant inspections nonproductive and derive no satisfaction, personal or otherwise, in routine repetitious activity with no measurable success. Until their basic insecurity about the value of a program is replaced by confidence and they receive some degree of satisfaction from their work, their efforts will not be truly productive. What can result from an outside evaluation is illustrated by the experience of the restaurant sanitation program of the Berkeley Department of Public Health.

Evaluation Surveys

In 1954 the city health department requested that the California State Department of Public Health evaluate the sanitary standards maintained by the eating and drinking establishments of the community.

The State health department team that conducted the survey was particularly conscious of the subjective nature of this type of evaluation. Every effort was made to standardize their procedure and to make their approach to the evaluation process as objective and uniform as possible. In many practice scorings and duplicate scorings, the team increased its objectivity, and scorings by its members varied only

slightly. It is difficult to be objective in this type of an evaluation; however, a survey appears, and has been substantially proven to be, the most objective way to evaluate programs such as restaurant sanitation.

Berkeley has had a restaurant sanitation program since the early twenties. In the survey of 1954 Berkeley had a mean score of 72.8. Neither in 1954 nor in subsequent studies was Berkeley's score compared with that of other communities which received a similar evaluation.

Evaluations using the same yardstick were performed in 1955 and 1956. The 1955 mean score was 73.7, and 1956, 73.1.

Following the 1956 evaluation it was decided that a change in program policies was indicated. At that time sanitarians lacked enthusiasm for the program, considering it more of a chore than a challenge. Two questions to be decided were: first, were the sanitary standards being maintained in the community satisfactory, and second, was the health department to continue a program which lacked vitality and was time consuming.

The scores in 1954, 1955, and 1956 indicated that no strides forward were being made although such variables as number of restaurants, size of sanitation staff, and effort expended remained almost constant. Perhaps if nothing were done, the score would remain the same. Without any supervision at all, some restaurants will maintain high standards, some, low standards, and the majority will be mediocre.

The question of why other programs, particularly housing, were approached with more enthusiasm and vitality than the restaurant program was answered. In housing, sanitarians had the ego-satisfying experience of success, of accomplishing something worthwhile. This was totally lacking in the food program.

Changes in Policy and Procedures

A number of staff meetings were devoted to revitalizing restaurant sanitation activities in 1956. These meetings brought about many changes in policy and procedure.

The system of keeping records was changed. In the separate folder kept on each restaurant, a record of all contacts between the health department and the establishment is filed chrono-

Figure 1. Distribution of scores of eating and drinking establishments, Berkeley, Calif., 1956 and 1958 surveys

logically. The contents include not only the routine inspection forms but also entries of re-visits, rechecks, telephone conversations, letters, complaints, or other communications such as commitments, compromises, or mandates.

When an inspection is made it is thorough and complete. The old, and in some localities perhaps, still common practice of noting only a few items had created a great deal of confusion and inefficiency. This practice was based on the idea that if one were to stress all of the deficiencies at one time, restaurant owners might be overwhelmed, and nothing would be accomplished. This has proved to be a false and damaging concept. At present, the proprietor is approached on a strictly business-like basis, all the deficiencies are pointed out, and new deficiencies noted as they occur.

Previously, when a sanitarian inspected a restaurant for the first time and informed the owner of several violations, he was often told that his predecessor had been coming in for 2 years and never mentioned them. By presenting an incomplete report, a sanitarian is not only being unfair to the proprietor, but also to his department and colleagues. The proprietor concludes that everything which is in violation has been noted and all else is satisfactory.

In cases which must be prosecuted, the importance of complete, thorough, and accurate records cannot be overemphasized. The reluctance of the district attorney's office to prosecute is understandable if the record is vague, indefinite, and nonspecific. Such records serve absolutely no useful purpose.

Figure 2. Comparison of selected physical defects in eating and drinking establishments, Berkeley, Calif., 1956 and 1958 surveys

Also poor notes and records make it difficult for another sanitarian to take up the relationship established by his predecessor at precisely the point at which it had been dropped.

Many sanitarians, new to the department, to the district, or even new to public health, insist on starting a completely new relationship with the proprietor and completely ignore previous contacts. The only conclusion that can be drawn from such an approach is that the predecessor's judgment was not trusted. This is an extremely wasteful, time-consuming procedure.

Also, a successor can pursue an objective for a particular restaurant once it has been established after a complete inspection that has been accurately and fully recorded. Once

the objective is reached, the only responsibility remaining is to maintain it.

In Berkeley, the public relations value of this businesslike approach has been notable. Sanitarians have reported that compliance is prompt; there is little if any misunderstanding. They have expressed the feeling that as individuals they have gained a greater respect from the businessman.

The followup procedure is extremely important. In the system established in Berkeley the recheck date is marked on a small card which accompanies the folder for each restaurant. The card is placed in a tickler file, and on the date specified it is pulled and the folder and the card given to the person who requested it. Each sanitarian keeps a calendar and sched-

ules rechecks according to other commitments. Each day's workload is scheduled and planned in advance.

The frequency of inspections is another item which has been drastically changed as a result of the 1956 evaluation survey. After the survey it was agreed that inspections be made every 2 months, or more frequently if necessary.

This step proved effective in getting the present program underway. It is felt now that the frequency of inspection can be left entirely to the discretion of the sanitarian. However, it was thought desirable that at least two inspections per year be made of those places receiving a minimum amount of service, the restaurants which consistently maintain high standards.

Figure 3. Comparison of selected operational defects in eating and drinking establishments, Berkeley, Calif., 1956 and 1958 surveys

These would be made to assure that previously noted high standards are continued, and also to keep sanitarians thoroughly familiar with the operation of each restaurant. The sanitarian is otherwise free to schedule inspections as he sees fit, permitting him to concentrate his efforts where they will be most productive, in the establishments with low scores in the survey. With these changes the program picked up momentum and interest was created. In December 1957, a little more than a year later, a request to the State was made for study of the restaurant program. As a part of this study, policy, local codes, frequency of inspections, supervision, records, and other items were discussed.

Those who conducted the study offered many interesting and pertinent comments which were brought to the attention of the staff. Those suggestions thought to be most important were incorporated into the program.

In September 1958, 2 years after the previous evaluation, the restaurant sanitation program was resurveyed, using the same yardstick and the same objective approach described earlier. Berkeley's mean score was 82.9, or an increase of almost 10 points (fig. 1).

Berkeley has established as an objective a mean score of 85. Once this goal is reached, it will become necessary only to maintain the status, which, theoretically, will require less effort than that required to raise it to this level.

Rough calculations indicate that this objective has now been reached, and any additional effort would result in diminishing returns. Berkeley has reached the practical maximum of achievement, and sanitarians can now devote the man-hours of time saved to other challenges of environmental health.

The survey was of particular value because it pointed out areas of emphasis rather dramatically. For example, the 1958 survey showed that 51.2 percent of the Berkeley restaurants

lost points because of poor food storage methods, an operational defect, and 41.9 percent lost points because of poor floors, a physical defect. On the other hand, it was found that rodents and insects were an operational problem in only 2.3 percent of the establishments, and only 1.2 percent lost points because of poor ventilation (figs. 2 and 3).

Although areas of emphasis would vary from department to department, these examples indicate what evaluation can mean in program planning. For sanitarians in Berkeley to spend a great deal of time on ventilation or rodent and insect problems would not be warranted. They must devote their efforts to instruction on good food storage methods and insistence on well-constructed floors.

Summary

Evaluations are essential to efficient planning in food sanitation programs. At least two methods of evaluation should be considered: first, cost versus value received, and second, a means of measuring achievement as progress toward a predetermined objective. Both cost and performance are necessary ingredients in making a meaningful evaluation.

There are many personal and emotional factors which affect evaluation. If responsibility for restaurant sanitation is to be a meaningful public health activity, it must be approached in a professional manner. An objective, and the present position in relation to the objective, must be established.

An appraisal by an outside agency, technically competent to critically evaluate a program and to measure achievement, is one method of accomplishing a portion of an evaluation. Evaluation can improve service to the restaurant industry of a community and add enthusiasm and prestige to the local health department's program.

The Radiological Health Program in Rensselaer County, N.Y.

LOUIS J. LANZILLO, B.S.

AVOID all unnecessary ionizing radiation. With this the objective, the Rensselaer County Health Department in New York State developed over the past 4 years a modest but effective radiological health program. Accomplishment of the objective is attempted by providing advice, guidance, and technical service in the use of ionizing radiation sources.

New York State became actively concerned with the health and safety aspects of ionizing radiation as a result of waste disposition problems of the early Atomic Energy Commission installations in the State. In 1952, the State health and labor departments took a census of shoe-fitting fluoroscopes. Under the then existing regulation 2 of chapter IX of the State Sanitary Code a program was initiated for controlling the specific hazards associated with the use of these machines. (As of July 1, 1958, the New York State Health Department outlawed the use of the shoe-fitting fluoroscope by unlicensed practitioners.) Both departments then appointed committees of experts to assist them in a study of the entire radiation problem in New York State. The State health department's Advisory Committee concluded that there was a significant and steadily in-

creasing radiation problem in the State and that the health department should prepare to meet this situation. This culminated in June 1954 with the preparation and acceptance by the commissioner of health of a program plan for radiological health. The objectives of this plan were education and training, regulation of radiation exposure, enforcement of laws and regulations, and research.

A radiological health section was subsequently established in the State department's bureau of environmental sanitation, and chapter XVI was added to the Sanitary Code, effective September 1, 1955, as the basis for a program of inspection, education, and correction. Chapter XVI is intended to control the "location or facility where radiation equipment is used or where radioactive material is produced, transported, stored, or used for any purpose." The regulations cover registration of radiation installations with the health officer having jurisdiction, definitions, construction, maintenance and operation, maximum permissible doses, personnel protection, medical examinations, patient protection, disposal of radioactive wastes, radiation instruments, handling of cadavers, monitoring of radiation installations, therapy rooms, warning signs, accounting for radioactive materials, radiation illnesses, injuries, emergencies, accidents, electrical hazards, vacated premises, and limitations on application of radiation to humans.

The interest of the Rensselaer County Health Department in radiation hazards was aroused

Mr. Lanzillo is a sanitarian with the division of environmental hygiene, Rensselaer County Health Department, N.Y. This paper is a revision of the one he presented at the 55th New York State Annual Health Conference in Lake Placid, N.Y., May 26, 1959.

early in 1956. The department at that time had no personnel trained in this new field, but the staff was able to keep abreast of developments by the division of environmental hygiene's in-service training conferences and by consultation with the radiological health section of the State health department.

Using for a mailing list the county health department inventory, which was incorporated in the State census, letters went to the operators of every shoe-fitting fluoroscope in the county alerting them to the hazards. Also, a letter was sent to all operators of dental X-ray equipment urging them to see that their units had filters with the equivalent filtration effect of 2 mm. of aluminum. Filters were obtainable at a local dental supply house.

In the latter part of 1956, the county health department sanitarian was given training in the mechanics and theory of radiation management by inspecting medical, dental, and veterinary X-ray equipment in the county jointly with a member of the State radiological health staff. The reports on these inspections were reviewed with State radiation officials. Since the county health department had no equipment for monitoring radiations, it had to use the State's equipment when available.

Early in 1957 the county health department requested an appropriation to purchase monitoring equipment. Denial of the request delayed implementation of the radiological program.

During this temporary delay, the department concentrated on personnel training. Courses in basic radiation physics and radiological health survey methods were provided by the radiological health training staffs of the Public Health Service and the Atomic Energy Commission at the University of Rochester and elsewhere, in cooperation with the State health department. These courses were attended by the sanitarian, who was to become the supervisor of the radiological control program, and the director of the division. A course on sanitary engineering aspects of nuclear energy was held at the Robert A. Taft Sanitary Engineering Center, Cincinnati, Ohio, and was attended by the director of the division of environmental hygiene.

Later that year, through the efforts of the county health officer and the director of the

division of environmental hygiene, a special appropriation was granted to purchase the following basic monitoring equipment: an ionization chamber "cutie pie," a Geiger survey meter, six direct-reading pocket dosimeters of varying ranges, a dosimeter charging unit, a micrometer caliper, and a stopwatch. The cost of this equipment was approximately \$817.

Program Elements

The responsibility for implementing the radiological health program was assigned to a sanitarian in the environmental hygiene division in addition to his other duties.

The first major undertaking was to determine where and in what quantities radiation was being used in the county. Registration of all sources of radiation with the local health department is required by chapter XVI of the State Sanitary Code. In Rensselaer County 52 operators voluntarily registered their installation following a press release by the State health department. It was suspected, however, that this number represented only a fraction of the sources of radiation.

To expedite registration, tearoff return postcards were sent to all other physicians, dentists, veterinarians, podiatrists, and osteopaths asking if they used X-ray equipment or radioactive materials. The list was assembled from the yellow pages of the telephone directory. A followup by telephone was made on those who did not reply, although the postcard reminder was relatively successful.

The survey revealed 111 installations of X-ray equipment as shown below. In addition, one hospital, one university, and one laboratory reported installations using radioactive materials.

Source	Number of X-ray installations	Number of machines
Medical -----	39	52 ¹
Dental -----	60	61
Veterinarian -----	5	5
Research -----	2	5
Other -----	5	5

¹ Includes 3 used for therapy.

Next, a letter was sent to operators whose installations were not registered asking them to register their equipment or materials immedi-

ately. To date, a total of 109 of the 111 operators have registered their radiation equipment. A few operators requested, and were given assistance in filling out the form.

Following the postcard survey and registration, a simple visible card file was set up on all radiation installations. Information on the card includes name of the installation, location, operator in charge, type of equipment, whether or not registered, and date of last inspection. The status of the installation is indicated by a colored tab to denote whether the installation was satisfactory or unsatisfactory.

Field investigations were the second major activity. Those undertaken at the beginning of the program were limited to shoe-fitting fluoroscopes, prohibited since July 1, 1958, dental units, and portable medical radiographic units. Field experience gained in company with the State personnel and the consultation service available from them and the division director helped build up the confidence of the supervisor. As confidence increased, activities were gradually broadened to include detailed investigations of X-ray departments in hospitals and laboratories.

An important adjunct of the field investigations is the education of the professional users of radiation sources to the significance of ionizing radiations, procedures for reducing radiation hazards, and application of improved techniques.

To assist users of dental X-ray equipment, the health department staff did some research in dental radiography, resulting in a suggested technique in which maximum protection from ionizing radiation will be provided, under the most practical conditions, for all persons concerned. X-ray procedures are patterned so that the operator is never in the direct path of "useful" beam for primary protection and his position utilizes distance and any available barrier for secondary scatter protection.

The procedure suggests: (a) the provision of a swivel armchair, similar to an executive-type chair, with an attached headrest, for use in X-raying the patient, (b) the location of the swivel chair near the X-ray unit, but, more important, against a wall in the room that faces an unoccupied area—the X-ray tube placed in line with the chair so that all X-ray exposures

are directed toward the chair which, to repeat, is located against the wall facing an unoccupied area, and (c) placement of the patient in the chair in any position desired because of the mobility of the chair. In a full-mouth series the operator can merely adjust the patient to the restricted direction of the X-ray tube and take the necessary exposures. This technique of positioning will prevent the operator from ever being in the direct path of primary beam. The operator must then assume a position as far as possible from the tube and patient and utilize any barrier in the room such as a wall or door for maximum protection from stray radiation.

Currently, the program is being expanded to include the safe management of radionuclides. The program supervisor attended a training course on hazards of radionuclides at the University of Rochester in 1958. He has also observed a representative of the Atomic Energy Commission on inspections of installations in Rensselaer County authorized to use radionuclides. This training has developed the program supervisor's familiarity with the uses of radionuclides in hospitals and laboratory research and the hazards associated with these materials. The use of radium in medical offices has not presented a problem in Rensselaer County because the survey revealed no authorized users.

Inservice training of the health department personnel in radiological health work continued as the program progressed. A particularly valuable course arranged by the New York State Health Department training section was given in a radiation workshop at the University of Rochester in November 1958. The session offered an opportunity for exchange of ideas and discussion of local experiences by those directly engaged in fieldwork in radiation control. Other such workshops are expected to be sponsored in various areas by the State health department.

Program Implementation

In the field investigations, about every type of X-ray machine that might be used in medical, dental, or veterinary practice has been encountered. Poor technique, insufficient filtration, or lack of cones were commonly found

in the installations. Some of the hazards associated with these units and the protective measures suggested follow.

Radiographic Units

A few old radiographic units with glass unshielded tubes are still in use by physicians and dentists. The department has been successful in discouraging the use of two such units. One dentist is buying a new 90-kv. unit, and another is having his X-ray work done by someone else.

One of the most common defects was the lack of adequate filters for the primary beam. The State Sanitary Code requires a total filtration equivalent to at least 2 mm. of aluminum. The filter absorbs the soft, less penetrating radiations, thereby protecting the patient from these dangerous rays. It eliminates scatter haze on film, and appreciably reduces stray radiation. This amount of filtration will not require an increase in the exposure factors to achieve a satisfactory film.

There was a conspicuous absence also of diaphragms or cones for collimating the useful beam. In some installations the collimating device was oversized. A diaphragm or cone of correct size in the useful beam serves to limit the size of the radiated area to that which is clinically necessary. For dental X-rays, the collimation should be adjusted so the patient is exposed to a beam no greater than 3 inches in diameter in order to protect the patient's eyes.

In conventional chest X-rays, operators were encouraged to protect patients from scatter radiation by draping an apron of one-half millimeter lead equivalent below the front of the cassette as an adjunct to close coning.

Frequently advice was provided for improving radiographic operational safety. In many instances the operator customarily stood either adjacent or close to the equipment, and sometimes directly in the path of the primary beam. For maximum protection from primary and stray radiation, operators are advised to stand as far as possible from the tube and the patient during an exposure. An extension cord on the timer button enables the operator to stand in an adjoining room or at least behind a shield. Operators were also informed that it is no longer necessary to use film requiring long ex-

posure. They were advised that modern fast film permits shorter exposures, thus reducing the dose to the patient and the stray radiation to the operator. The shorter exposure time also saves wear and tear on the unit.

When a dentist is contemplating purchase of a new X-ray film unit, the 90-kilovoltage unit should be considered in place of units operating at 45-70 kv., because the exposure time is reduced from the usual 1.5 seconds to 0.5 second. An 18-inch focal distance from the skin with a long lead cone device (15 inches) and 3 mm. of aluminum for filtration purposes will cut down skin exposure and reduce gonadal dose considerably.

Fluoroscopic Units

Diaphragm shutters and tubes of fluoroscopic units were often found off center from the viewing screen. Under these conditions, the useful beam extended beyond the fluoroscopic screen and struck the operator. Centering the beam, of course, was recommended. In addition, operators were told to limit the shutters so that when fully opened there was a visible black margin of at least one-fourth inch around the screen at the maximum working distance from the table. It was also suggested that the smallest possible aperture of fluoroscopic screen be employed during examinations since both the volume dose and the scatter increase more rapidly than the dimensions of the fluoroscopic field.

Fluoroscopic screens frequently were not completely interlocked with the X-ray tube. The screen could be adjusted in various positions so that not all of the primary beam is intercepted by the protective lead glass of the viewing screen. Installation of a pin or hinge between the screen and screen frame was advised to provide an interlock with the tube.

As with radiographic units, absence of adequate aluminum filters was also common.

Leaded aprons and gloves in unsafe condition were occasionally found. Protective clothing for the operator and assisting technician are required to be checked periodically by the person responsible for radiation safety. In horizontal fluoroscopy, to assure adequate protection from scatter, it was recommended that an apron of one-fourth millimeter lead equivalent

hang between the patient and the fluoroscopist. This is in addition to a protective apron worn by the operator.

The time required to adapt the eyes to darkness prior to a fluoroscopic examination is particularly irksome to the busy physician. Dark adaption is essential because it permits adequate examination of the patient with the least possible radiation exposure. A dark adaption period of 20 minutes with polaroid glasses was recommended. Improvement continues up to 20 minutes but a minimum of 10 minutes of dark adaption is necessary.

Few fluoroscopic units encountered in the field were provided with a built-in integrating timer, although units installed after September 1, 1955, in New York State are required to have such a device to interrupt the circuit after 4 minutes of exposure. Operators of units installed before that date can satisfy this requirement by purchasing an interval timer, for less than \$10, and manually setting the clock for the 4-minute exposure. This control alerts the physician and reduces the possibility of over-exposure of the patient.

Sometimes the dosage rate at the table top exceeded the maximum 10 roentgens per minute. This unsatisfactory condition can be corrected by lowering the milliamperage, by adding more filtration at the tube port, or by increasing the distance between the tube target and table panel.

Operators are also advised of the availability of intensifying screens which make it possible to reduce the dose to the patient as well as to the operator.

Blanket Registration

On May 20, 1959, a blanket registration was granted to Rensselaer Polytechnic Institute, one of the leading educational institutions in the State. Blanket registration is the authority for self-policing in compliance with the State health and safety regulations. This is considered the most practical method of accomplishing the objectives of the State Sanitary Code in view of the institution's increasing use of radionuclides and radiation-generating equipment in research and teaching. Special radiation facilities include a subcritical assembly reactor, a Van de Graff proton accelerator, a

betatron accelerator, a Cockcroft-Walton accelerator, and several X-ray diffraction units.

As a result of health department recommendations over a period of 3 years, the institution organized a radiological safety committee and appointed a radiological safety officer. A draft of the institution's proposed administrative control and radiological protection procedures was submitted to the county and State health departments for review and comment. The final draft, incorporating suggested revisions, was officially approved by the institution April 24, 1959. The procedures are divided into three parts: administrative, general radiological protection, and specific radiological protection. A unique feature is that the last part can be changed at any time without amending the entire document.

The radiological safety officer of the university is empowered to make inspections and impose additional requirements and emergency measures he deems necessary to maintain high standards of radiological safety. The radiological safety committee is giving considerable attention at present to radioactive wastes. The current plan is to use a commercial waste disposition agency in lieu of a burial area located in the county. Radioactive wastes at the moment, however, are being stored in a shielded storage room at the institute and are periodically monitored by the radiological safety officer.

Approval by the health department is required for the disposition of radioactive wastes by ground burial. Routine monitoring is specified and maximum concentration limitations are established. In the event of fires, accidents, unauthorized entry, thefts or losses, each such instance is to be reported to the radiological safety officer who in turn advises the Rensselaer County health officer. If the radiological safety officer cannot be reached, the county health officer is to be advised. The county radiological health program is geared then to protect the citizens from any unfortunate consequences that might result from the mishandling of radionuclides or radioactive wastes.

Summary

The New York State Department of Health initiated activities in 1952 to control radiation

hazards. The Rensselaer County Health Department is carrying out this program in Rensselaer County.

The program, under the supervision of a trained sanitarian and with the basic monitoring equipment, consists of registration of installations, a visible card file record system, and inspection of radiation equipment. Activity is presently limited to radionuclides and certain other radiation sources, such as accelerators. The staff, however, is continually increasing its working knowledge and competence to carry out better the legislated responsibilities.

Much of the program consists of education in the safety values of shielding, distance, restricted exposure time, coning, filtration, and protective clothing. Although protective

means are available, the county health department must work tirelessly to develop safe habits and promote safe facilities among radiation users. To be effective this educational program seeks to stimulate self-discipline.

Rensselaer County's radiological health program has been developed with currently available space and staff and with an expenditure of less than \$1,000 for equipment.

This program is another demonstration of the advantages held by a modern county health department employing only qualified professional personnel. Such a department can adjust its activities to provide optimum public health protection in our ever-changing environment.

Kimble Award

The deadline for nominations for the Ninth Kimble Methodology Research Award is June 1, 1960. The award, \$1,000 and a silver plaque, is given annually in recognition of the application of scientific knowledge to the public health laboratory.

Candidates must live in the United States, its territories, or Canada. Their work should be either a fundamental contribution which serves as a baseline for development of diagnostic methods within the province of the public health laboratory or the adaptation of a fundamental contribution to make it useful in a diagnostic laboratory.

Authors, their associates, or others may make nominations. Studies with more than one author will be accepted. The nominations must be accompanied by six summaries and a bibliography, also six reprints if available. A statement justifying the recommendation of the work and a letter of transmittal are required. Documentary evidence and related material should not be signed by the nominator. None of the material submitted will be returned.

The Kimble award, established by the Kimble Glass Company of Toledo, Ohio, and sponsored by the Conference of State and Provincial Public Health Laboratory Directors, will be presented at the annual meeting of the conference in San Francisco, Calif., in October 1960.

Send all nominations to: P. R. Edwards, Chairman, Nominating Committee, Kimble Award, Communicable Disease Center, P.O. Box 185, Chamblee, Ga.

United States-Mexico Border

Public Health Association

CONFERENCE REPORT

A border 2,000 miles long, crossed 75 million times in the course of a year, gives rise to human relation problems with direct or indirect bearing on the health of communities and the individuals who live in them.

ABRAHAM HORWITZ, M.D.

By interlinking public health planning along their common border, the United States and Mexico have been taking a realistic approach to the fact that disease recognizes no political boundary. The vehicle for their joint health efforts, the United States-Mexico Border Public Health Association, has for more than 17 years attacked issues of common concern through conference discussion and committee studies and has organized integrated action.

The 17th annual meeting of the association held in Brownsville, Tex., and Matamoros, Tamaulipas, Mexico, between March 30 and April 3, 1959, was attended by more than 300 public health workers. Speakers and delegates delineated the scope of public health responsibility, analyzed the interplay of public health and environmental elements, marked out areas for intensified effort, and reported achievements in control and research.

Presiding over the opening plenary session, Dr. Abraham Horwitz, director of the Pan American Sanitary Bureau, World Health Organization Regional Office for the Americas, emphasized that the economic matrix of a society nourishes or stunts the people's health and conversely the degree of progress of a community hinges largely on the abundance of human energy derived from sound health. In extensive parts of the Americas, he said, deficient nutrition and scarce water supply and other unfavorable conditions drain off the lives and energy needed to transform those conditions. Public health techniques must harmonize with all other activities which condition the individual's well-being. Among his other recommendations was the integration of all community public health activities within the local health agency, using the family as the basic unit. Public health workers should be aware, he

believes, of the trend toward pooling the hemisphere's spiritual and material wealth. As a short-run international health aim, he proposed an attack on diseases with strong economic ramifications; long-run goals should focus on creating and expanding local and national health services and training professional personnel.

Recognition of the frontier as "a two-way street" rather than as a barrier, observed Dr. John C. Entler, Assistant Surgeon General for Program, Public Health Service, is contributing, through the exchange of venereal disease contact data, to control in areas far from the border as well. He urged each health agency and clinic providing services to braceros to function also as a venereal disease control station. After illustrating how venereal disease control activities have pioneered in casefinding and administrative techniques, he pinpointed one of the current challenges as the proportional increase in infectious syphilis among persons under 20 years old.

Another conference highlight was a roundup by Dr. David E. Price, Assistant Surgeon General and chief of the Bureau of State Services, Public Health Service, of health research in the United States during 1958, particularly in cancer chemotherapy, psychopharmacology, new drugs, and studies of viruses in the cause of cancer. Among current and anticipated challenges to public health planners he named staphylococcal strains resistant to antibiotics, shortages of medical personnel, and the negative health facets of urban environment.

For the past 4 years, he observed, there has been no material rise in life expectancy at birth. This expectancy can be increased mainly by maintaining the health and vigor of the growing number of persons of middle age and older.

Dr. Domingo Cervantes Gonzalez and co-workers summarized their activities in the Mexican National Antimalaria Campaign during 1958 in Tamaulipas, Mexico. An account of the construction and development of the Hermoso Valley, Mexico, water system was presented by Alfredo Sahagun Sahagun, the system's manager. During the session, the participants selected Hermosillo, Sonora, for their 1960 meeting.

Following are summaries of selected papers presented at the conference.

Mexican School Hygiene Covers Broad Scope

A function of school hygiene in Mexico, in promoting students' physical, mental, and moral health, is to monitor the environment in and around the school for unwholesome elements, asserted Dr. Mannel Aveleyra Arroyo de Anda, director general of school hygiene, Ministry of Public Education, Mexico City. Hygiene units, he explained, watch the neighborhood for sale of unhygienic foods, inappropriate businesses, and unsafe traffic conditions.

Relating highlights of Mexico's 77-year experience with school hygiene, Aveleyra revealed that Aztec children were taught rigid hygiene practices and were lightly clothed for health and growth. Colonial Mexico had medical inspection of Royal University students and smallpox vaccination, leading to the disease's ultimate eradication. Correctional houses, he said, date from the postindependence era when juvenile delinquency was serious, and a school for deaf-mute children was founded by Emperor Maximilian. A pedagogic-hygienic congress in 1882 produced the scientific, organized application of school hygiene, followed not long after by the setting up of a special unit of medical and hygienic inspection for schools.

School hygiene, stated Aveleyra, aims to promote in students "assimilation of learning, adaptation to the prevailing medium, hygienic habits, and sanitary convictions." Since teachers are basic supports, students of normal schools are screened for the mentally and physically unfit and teaching candidates are periodically checked and provided health services. Throughout their careers, teachers' health is watched; they are given hygiene publications, courses, and lectures. Also, they take active part in routine hygiene work. In schools without hygiene services, they receive instructions for their own health care and pupils' hygiene. All kinds of workers on school premises come under the hygiene program.

Following set norms, pupils are given health education and guidance in psychic and biological development, including medical assistance and rehabilitation. They receive medical-prophylactic examinations and are classified and vaccinated. In 1958, stated Aveleyra, the hy-

giene department examined about 773,000 pupils, of which roughly 154,000 were found with a disease.

Among the activities he described was the 1953 antituberculosis campaign, in which school children sold almost 3 million stamps, thus raising funds to start an antituberculosis dispensary for the schools. In school festivities, such as School Hygiene Week, parents mingle with school personnel and pupils and are exposed to information on hygiene. Home visits are made by committees on school hygiene composed of students elected by classmates, trained by school medical personnel, and supervised by a selected teacher.

Aveleyra mentioned that the work of each school medical zone, comprising schools totaling 4,500 to 5,000 pupils, is planned with flexibility yearly in advance by the department of school hygiene and school authorities.

Encephalitis in Texas Had Economic Impact

The three encephalitis viruses, first found concurrently in south Texas in 1941, have been an important public health challenge there during 3 of the last 5 years. This was mentioned in a brief review of findings on these viruses in Texas by Dr. J. V. Irons, Dr. Richard B. Eads, James E. Grimes, and Thelma D. Sullivan, division of laboratories, Texas State Department of Health. One reason, they said, lies in the relatively abundant water supply in the Lower Rio Grande and extended irrigation of the Texas High Plains area which favored propagation of mosquito vectors. Western and St. Louis encephalitis are most active in Texas; eastern, the least.

Small outbreaks occurred in 1944 and 1952. Then in 1954 an outbreak was followed by 500 cases later that year in Hidalgo County, mainly from western encephalitis. The St. Louis variety predominated in a large 1956 outbreak in the Texas High Plains and caused a lesser one in Cameron County in 1957.

In the Hidalgo and Cameron County outbreaks, illness ranged from numerous subclinical cases to an occasional fatality, affecting all age groups but mostly young-adult and middle-aged men. The economic impact was heavy.

RESOLUTIONS

Among the resolutions adopted during the 17th annual meeting of the association were those dealing with:

- more intensive efforts toward control of venereal disease in border cities, including serologic testing of migrant labor, greater use of municipal, State, and Federal resources, and extended training.
- recommendations that infectious syphilis cases be considered medical emergencies, calling for exhaustive epidemiological study and rapid control.
- intensification and expansion of training for border health personnel, including opportunities for observation of conditions and health practices in both countries.
- strengthening health information exchange on both sides of the border.
- for emergency treatment of diarrhea, adequate equipment, physical facilities, and expert personnel, in border health centers.
- possibilities of setting up a scientific committee of experts from both countries to make an epidemiological study of encephalitis along the border and to suggest control measures.

They also pointed out the difficulty of differential diagnosis of encephalitis and aseptic meningitis.

Says Goat Product Output Should Be Industrialized

In large areas of Mexico, the entire goat population may have brucellosis, reported Dr. Alfonso Elizondo of the Rural Cooperative Medical Service in the Mexican Ministry of Health, Mexico City. Rapidity of contagion keeps infection high, he explained, with consequent intensification of health and economic hazards to farmers. Of bovine origin, the disease is under gradual control through pasteurization and livestock vaccination.

Elizondo holds that the only practical way to control *Brucella melitensis* from goats is to remove the animals from farmers' living quarters some distance to communal corrals and to organize on a cooperative basis groups of farmers for animal care and small industrial plants for

making goat products. Not only will this reduce brucellosis from animal contact but that from atmospheric dust as well since goat refuse will be far from farm homes. Industrial handling of goat products will control the disease acquired via food. He pointed out that the plan required organizing communities, finances, product distribution, and utility allocation.

Another control technique he mentioned is goat vaccination with live vaccine, so far successful where adequate facilities for evaluating findings exist, as in Comarca Laganera.

Rabies in Wildlife Blocks Eradication Elsewhere

Though rabies in dogs has been steadily reduced in border areas, the disease in wildlife during the last 10 years has climbed. This has kept the rate of infection among the Nation's domestic animals almost stationary despite public health measures, stated Dr. Donald Miller, veterinarian in charge of the Animal Disease Eradication Division of the U.S. Department of Agriculture, Phoenix, Ariz.

The menace to the livestock industry and to public health calls for a triple-pronged attack: State and Federal control of the disease in urban pets; an attack by the Fish and Wildlife Service and similar agencies on wildlife rabies; and cooperation of the U.S. Department of Agriculture with these authorities, particularly in protecting livestock and poultry. He described Department of Agriculture activities as including epidemiological studies, aid in drawing up local regulations and in spreading control information, and vaccinating dogs on Indian reservations. He also mentioned inspecting, licensing, and testing rabies vaccines.

Among border States, Texas is hardest hit by rabies in domestic animals, said Miller, citing the 49 cases reported there in 1957 and the 74 in 1958. He gave these national figures for 1957: 654 cattle, 24 horses, 13 sheep, 16 swine, and 12 goats. In 1958, reports cover 839 cattle, 37 horses, 34 sheep, 24 swine, and 6 goats.

Rabies Control in Texas

Dr. George A. Martin, veterinary public health division of the Texas State Department of Health, attributed an increase in rabies cases

in Texas in the first quarter of 1959 over the comparable 1958 period to a rise in the number of rodents and other small animals and therefore in the population of predatory animals, such as foxes, coyotes, wolves, and skunks.

In 1958, canine rabies cases totaled 236, said Martin, compared with 52 cases in the first quarter of 1959. For cats, he gave the figures of 21 and 20, respectively, and, after pointing out the difficulties in accurately gauging the extent of wildlife rabies, he estimated comparable totals of 106 and 52 for foxes; 45 and 35 for skunks; and 23 and 27 for cattle.

On the request of local authorities, Martin's unit helps set up rabies control concentrating on immunizing the dog population, controlling stray dogs, and abating the wildlife reservoir when indicated. In an analysis of several local successes and failures in control programs, he mentioned the pitfall of trying to finance control activities through high-priced dog license fees. Registration and immunization slacken as a result, he said. He recommended instead free dog registration as an initial control measure. Success in controlling rabies leans heavily on public education, he concluded.

Salmonella Still Thrives In Contemporary Setting

Modern ways of preserving and transporting food are fraught with the danger of allowing contamination with *Salmonella* organisms and of promoting rapid dissemination, in the opinion of Dr. Carl D. Heather, Ruth Keaton, H. D. Brethower, and Joseph M. Murphy, Jr., of the Texas State Health Department in Austin.

They cited the rise in number of isolates found in Texas in the last 5 years and a parallel increase in serotypes, which they attributed in part to the import of raw materials from abroad and to returning tourists. The rise in *Salmonella* reading isolates reflects a nationwide trend, they said. Among the outbreaks they reported were one with *Salmonella oranienburg*, the most commonly isolated serotype, and others with the rare *Salmonella chester* and *Salmonella blockley*.

They cautioned against too rapid incrimination of infection sources of outbreaks because some types are so common, recommending

phage typing for tracking down these sources. With all our emphasis on hygiene and our sanitation weapons, *Salmonella* still thrives, they commented.

Dog Food as Infection Source

Dog food as an important source of *Salmonella* infection in dogs is the subject of an ongoing study reported by Dr. Heather and Barbara Nobles of the department's division of laboratories. They believe that canine infection may be an important cause of human salmonellosis.

Inspired by a 1955 study by Galton and associates, Heather and Nobles sampled 14 brands of dog food from retail stores. Three were positive, one consistently so, and each of the others yielded *Salmonella* from one box out of six tested. To date, Heather and Nobles have found 400 isolates representing 18 serotypes, 12 of which were found in human stools.

Samples from each box cultured in tetrathionate broth and streaked with *Salmonella-Shigella* and brilliant green agar at 24- and 48-hour intervals yielded 9 serotypes; another trial with 7 enrichments and daily streaking for 4 days gave 15 serotypes. No salmonellae were found in formed or pressed foods.

Salmonella dublin Outbreak

Prefacing an account of a *Salmonella dublin* epidemic in southern California in the autumn of 1958, Dr. Robert D. Courter, assistant chief of the Veterinary Public Health Section, Communicable Disease Center, Public Health Service, stressed the economic and public health hazards posed by this organism.

Contrasted with its current importance elsewhere, the organism has low incidence in the United States thus far, and apparently appears only in the west.

In adult cattle, *S. dublin* may cause sporadic outbreaks and epidemics associated with other weakening conditions, especially in asymptomatic carrier animals. Infection in calves, severest among those up to about 3 months of age, is favored by overcrowding, poor nutrition and sanitation, and inadequate reaction to antigenic stimuli.

The California outbreak consisted of 11 laboratory-proved cases and 19 suspected, all

traced to a certified raw milk dairy. *S. dublin* was isolated from 3 of a herd of 400 cows. Courter remarked that only repeated bacteriological tests of feces are reliable in detecting infected and carrier animals. Recovery of the organism from milk, the usual medium for man-to-man infection, tends to be from fecal rather than mammary contamination.

Courter feels that the epidemic has underlined the need for close work between authorities concerned with animal health and those dealing with human health.

Says Diarrhea Hazard Is Underestimated

Neither physicians nor the public ascribe enough importance to diarrhea among children, asserted Dr. Reynaldo A. Garza, pediatrician in the coordinated service of health and assistance of Nuevo Laredo, Tamaulipas, Mexico. In his city alone, the disease causes 50 percent of all children's deaths, he said, commenting that the causes of many cases of diarrhea remain uncertain, but that some degree of malnutrition was a factor in all these deaths.

Garza proposed, for cities like his with health centers, a unit for pediatric emergencies staffed with experts in required procedures. It should be open to all at all times.

Comparing statistically deaths among children under 5 years old in Nuevo Laredo with those in several world areas, he remarked that his city's figure of 40.2 percent of all deaths lies closer to Africa's 64.4 percent than to 8.9 for the United States. Of each 1,000 live births in Nuevo Laredo, 45.96 died from diarrhea and 6.09 from malnutrition. He also observed that the rate of 12.64 for deaths from lesions due to labor, dystocia, or premature labor should stimulate further obstetrical studies.

Garza reported a Mexican study of 12,000 coprologic specimens showing first in order of frequency the *Salmonella* species: *typhimurium*, *anatum*, and *derby*; and next the *Shigella* species: *flexner*, *sonnei*, and *boydii*. In a 1958 study in Nuevo Laredo, 32 specimens had non-pathogenic *Escherichia coli* in 11 samples and *Paracolobactrum* in 4. He announced that findings of the National Pediatrics Association of Mexico in a nationwide investigation of the

etiology of infectious diarrhea has been scheduled for publication.

Level of Hog Use Is Key To Leptospirosis Rate

The rate of human infection with leptospirosis of porcine origin hinges on the total number of hogs intensively exploited rather than on the total hog population, stated Dr. Manuel V. Ramirez of the Institute of Animal Investigations, Palo Alto, Mexico. He recommended stringent measures for eliminating the disease in Mexico, emphasizing that control should start with the hog.

Piggens should be well drained, sunlit, and well ventilated, with cement floors, abundant running water, and antirodent equipment. Measures should include periodic disinfection, isolation of newly arrived hogs until shown free of the disease, periodic testing, immunization, and treatment of carriers with antibiotics.

Discussing serotypes pathogenic to man, Ramirez observed that rodents are primary reservoirs for most, and that transmission to hogs is through contaminated food, water, or soil. Among the characteristics of leptospirae are survival for more than 10 days in water with little chlorine and longer periods in alkaline soils, death in less than 10 minutes from radioactive ultraviolet rays, less than 10 seconds in 70° C. of dry heat.

Leptospira in the hog's blood, said Ramirez, favors infection of slaughterhouse workers; in an Australian study, 76 percent of such workers showed antibodies to two serotypes. In hog-producing Iowa, a study showed 16.4 percent of veterinarians had antibodies, and in Missouri, 5.2 percent.

Urges Tightened Laws For TB Control

The weak link in tuberculosis control along the border has been in applying legal restraint on recalcitrant patients, according to Jack C. Postlewaite, director of the tuberculosis division, El Paso City-County Health Department, Tex. He commended local physicians, however, for almost unanimous cooperation in reporting tuberculosis cases during 1958.

Postlewaite observed that El Paso is exposed to the disease from both human carriers—the so-called cured and arrested cases from nearby sanatoriums—and bovine, from Mexico, where it is endemic.

Postlewaite stated that deaths from tuberculosis have declined more rapidly than the case rate in recent years. This is explained both by improvements in treatment and in case-finding and reporting. Approximately 300 patients were in the tuberculosis hospital in 1952 compared with about 700 in 1958. This rise he attributed to intensive study of a large population of potential patients. When, for example, a meningitis prophylaxis study was conducted with Federal funds among 189 patients, a concurrent rise of about 300 percent was reported in the disease's incidence among school children under age 15. Other special studies were on 397 tuberculosis contacts, with Public Health Service aid, patch tests on 10,421 children, and another using X-ray mobile units which reached 6,505 persons in the county in 1958.

Postlewaite pointed out that in 1948 hospital tuberculosis cases were evenly distributed among minimal, moderately advanced, and far advanced. Since 1952 moderately and far-advanced cases have decreased, and minimal have increased 300 percent since 1955.

For developing tuberculosis control and therapy, Postlewaite's recommendations included:

- Local ordinances requiring X-ray surveys of food handlers; enforced isolation of positive pulmonary cases; appropriate legal action to hospitalize and treat recalcitrant active cases.
- Frequent public health nurse visits to homes of suspected persons; good contact studies by X-ray, skin tests, and gastric or sputum culture studies and active tuberculin skin tests of school children under age 15, and X-ray screening of older persons.
- Prohibiting tuberculosis suspects or persons with so-called arrested or cured disease from exertion until three sputum and three gastric cultures are reported negative.
- Skin tests (Mantoux) of all patients attending the well-baby clinic, at yearly or preferably 6-month intervals.
- Required regular examination, by the physician and tuberculosis control nurse, of a case

registry for control and treatment of all cases observed during the year.

- A pulmonary tuberculosis unit for isolation and therapy in a general hospital operated by the city and county, which may be used for temporary isolation and detention before transfer to the State hospital.

- A preventorium for isolation of contact children and a chronic disease hospital for patients with negative sputums but with crippling pulmonary or cardiac conditions secondary to the disease.

Screening for tuberculosis at the well-baby clinic in El Paso was described by Elizabeth Marcus, tuberculosis coordinating nurse in the El Paso City-County Health Department.

In addition, said Marcus, family members of patients are asked to the clinic for X-rays or skin tests. From the well-baby clinic following this screening routine, she announced, nine children were put under preventive treatment in 1958.

Sees Isoniazid Prophylaxis Only for High Risk Cases

Because of today's limited risk of tuberculous infection, the practicality of using isoniazid as a prophylactic among tuberculin negatives generally was questioned by Dr. Francis J. Murray, special consultant in the tuberculosis program of the Public Health Service. Its use could be foreseen where exposure is great and unavoidable, however. He mentioned large-scale studies of naval recruits indicating less than 6 percent tuberculin positives, a drop in infection prevalence to about two-thirds of the rate among them in 1950.

Murray's comments followed his review of a series of controlled studies conducted by the Public Health Service.

A longitudinal study of the chemoprophylaxis potential of isoniazid on 2,750 children with asymptomatic primary tuberculosis operated in 33 pediatric clinics in the United States, Mexico City, San Juan, P.R., and Toronto, Ontario, beginning in 1955. Administrators carefully assigned children to groups receiving isoniazid or comparable groups taking placebo, in a "double-blind" manner: neither subject nor investigator knew which were the controls.

Daily doses of isoniazid were from 4 to 6 mg. per kilogram of body weight. About 60 percent of each group were less than 4 years old, 10 percent less than a year, and the rest ranged up to 16.

Results of clinical, laboratory, and X-ray examinations made monthly the first year and quarterly the second were evaluated by a board of six investigators selected by all such participating workers. The first year, 2 definite complications showed in the isoniazid group compared with 27 among the controls. In the second year, among the 750 taking isoniazid and 740 taking placebo, the figures were 3 and 6.

A subsequent study begun in 1957 has covered about 28,000 household contacts in cooperation with 37 health departments in the United States and in Juarez, in 16 centers in Puerto Rico, and 27 villages in Alaska. About 3,500 of these contacts are in border States.

Members of households with new cases are X-rayed and tuberculin tested. The contact population is divided at random into matched groups by household size, one to receive isoniazid and the other, placebo. The study is also double blind to eliminate bias in evaluating findings.

Murray anticipates major findings only from longer observation. Rather than reexamination at the year's end, the study checks tuberculosis incidence and deaths in contacts' localities against the roster of participants and will periodically locate and thereby determine participants' general health status, possibly through commercial credit facilities.

In mental institutions, other studies covered 5,521 participants in 25 Wisconsin county hospitals and 8,360 patients in Milledgeville State Hospital. In Michigan, 3,800 are in an ongoing study, as are others in Massachusetts.

Murray observed that about 70 percent of the 85,000 new tuberculosis cases each year in this country may have been tuberculin positives before. Evidently, the disease is most often endogenous, he stated, citing in support a Danish study also indicating a higher risk for tuberculin positives than for negatives. This possibility and the constantly decreasing risk to tuberculin negatives make the prophylaxis studies especially relevant to tuberculin positive

subjects, he feels. If the studies' tuberculin positives are at decreased risk after year-long isoniazid intake, the drug will benefit markedly those now infected and indirectly cut the infection risk among those not infected, concluded Murray.

Few Bracero Health Views Changed by Work in U.S.

Health attitudes and practices of contract farm laborers from Mexico, or braceros, are not significantly changed by work in the United States, according to a survey of 1,100 of such workers reported by Henry P. Anderson, research public health sociologist, School of Public Health, University of California, Berkeley.

Designed to yield demographic, theory-oriented, and program-oriented data for public health workers serving braceros, the project was financed mainly by a Public Health Service grant. Interviewing was conducted at the El Centro, Calif., reception center, which, Ander-

son pointed out, draws mainly from one of several areas supplying these workers. The control group was made up of braceros newly entering this country.

Findings showed that the typical bracero:

- Whether single or married, had about six dependents and came from a small town or village in which he had lived all his life.

- Tended to use medical services more for scientifically recognized diseases than for folk illnesses.

- In selecting type of therapy, was influenced by economic considerations.

- Tended to be unclear about disease prevention and preventive activities of health agencies.

- Knew about origins of venereal disease but not tuberculosis, which causes the greatest number of bracero rejections.

- In choosing a physician, valued efficiency and ease of communication over personal qualities.

Pond Receives Winslow Award

M. Allen Pond, Assistant Surgeon General of the Public Health Service since 1958, has been presented with the C.-E. A. Winslow Award by the Connecticut Public Health Association.

The award, given annually to a Connecticut individual, group, or organization for an outstanding contribution in public health, is based on the ideals set by the late Charles-Edward Amory Winslow, bacteriologist, health educator, historian, pioneer in public health, author, and teacher.

Mr. Pond joined the staff of the Secretary of Health, Education, and Welfare in 1953, after serving 2 years as coordinator of community facilities services in the office of the Surgeon General. He has been a commissioned officer of the Public Health Service

since 1942, except during 1946-48 when he was assistant professor of public health at Yale University. In 1949 he was appointed chief of the Division of Engineering Resources.

Mr. Pond took a bachelor of science degree in 1935, and a master of public health degree the next year, from Yale University, where he continued on as a teacher of public health until 1942. He has been an officer in the American Public Health Association, the Yale Alumni in Public Health, and Loomis School Alumni Association.

A prolific author, he has served on the boards of *Public Health Reports*, the *Sanitarian*, and of official and private organizations connected with community building and planning.

Current Concepts on Control Of Diarrheal Disease

MELVIN H. GOODWIN, JR., PH.D.

THE URGENCY of meeting the public health challenge presented by diarrheal disease in States on both sides of the Mexican border was emphasized in a report prepared at the 1958 meeting of the U.S.-Mexico Border Public Health Association. That report enumerated available control measures and outlined the necessity for more precise delineation of problems and for development of more precise procedures against specific pathogens. The present paper is related especially to one of the points covered in the report: What assumptions regarding etiology and epidemiology allow us to proceed to a control program where laboratory facilities are missing? Some of the implications to control are suggested by results available thus far from studies on the etiology of diarrheal diseases at Phoenix, Ariz.

Recognized Pathogens

The work at Phoenix was designed to provide information on the current association of recognized pathogenic agents with diarrheal diseases. Previous studies in the southwest indicated the prominence of shigellae in the etiology of enteric infections. Investigations conducted by Hardy and Watt (1) from 1936 to 1938 indicated that these pathogens were isolated from 76 percent of the severe cases and 58 percent of the milder cases for all age groups. In recent years, cursory observations and a few studies specifically designed to determine what

etiological agents are currently responsible for diarrhea suggested that pathogens other than *Shigella* probably were of relatively more importance as causes of illness and death (2).

Infant deaths attributable to diarrheal disease in the United States receded from about 12,500 in 1941 to approximately 5,000 in 1956 (see chart). In the last few years, however, the rate of decline has diminished and the annual incidence appears to have stabilized at about 5,000 deaths. If this indicates that the maximum effectiveness of available control measures has been realized, further reductions in diarrheal diseases may depend upon development of more effective control methods or upon wider and more intensive application of existing measures. Prerequisite to either course is a redefinition of the problem based on knowledge of etiological agents currently responsible for diarrhea and of the appropriateness of available control measures for areas where problems are now most acute. Consequently, the first investigations at Phoenix were designed to determine the current association between recognized pathogens and diarrheal symptoms.

Results from initial studies, which were reported elsewhere in detail (3), may be summarized briefly. Intensive examinations for pathogenic enteric bacteria were made on specimens from 630 persons with symptoms of acute diarrhea for which treatment was sought. Approximately 67 percent of these persons were less than 1 year of age. Recognized bacterial pathogens were isolated by a single examination from 57 percent of the cases. *Shigella* organisms were recovered from 26 percent, enteropathogenic *Escherichia coli* from 31 percent, and *Salmonella* from 7 percent. About 90 percent of all enteropathogenic *E. coli* and 40 percent of the *Shigella* recovered were from infants less than 1 year old. The cases from which etiological agents were not recovered showed no characteristic distribution with respect to age of patient or month of occurrence.

The need for further research is indicated by the fact that no recognized pathogens were detected in approximately half of the acute cases studied. In addition to searching for unrecognized pathogens, attention must be given also to the possibility of etiology unrelated to infectious agents. Not only were the

Dr. Goodwin, who is chief of the Phoenix Field Station Section of the Communicable Disease Center, Public Health Service, summarizes in this paper material he presented to the U.S.-Mexico Border Public Health Association meeting on March 31, 1959, in Brownsville, Tex.

A Spanish version in summary form appears in the February 1960 Boletín of the Pan American Sanitary Bureau.

Number of diarrheal deaths among infants under 2 years of age, in the United States, from 1941 to 1956

majority of acute cases in the Phoenix studies in infants less than a year old, but the highest mortality from diarrhea characteristically occurred among infants during the first few months of life. Data available do not indicate whether or not the inherent virulence of specific pathogens associated with diarrhea of these young children is responsible for the high mortality or whether unfavorable prognoses result from other circumstances, for example, the rapid dehydration, malnutrition, or synergistic effect of other organisms. Furthermore, accumulation of additional information on the epidemiology of certain pathogens, *E. coli*, for example, is necessary to enable development of specific control measures.

Control Measures

Obviously, continuing investigations and development of more effective control measures are necessary to achieve the ultimate goal of control and eradication of diarrheal diseases. Public health workers recognize, however, that much can be done in the meantime to meet current problems that should not wait until pro-

cedures are devised that assure attainment of the more remote objectives. Although its relative prominence has apparently diminished, *Shigella* still seems to be the dominant etiological agent of summer diarrhea in the areas investigated. Traditional control measures, such as provision of water supply within individual homes, general environmental sanitation, promotion of breast feeding, health education, and maternal and child care, are of proved value in reducing these infections. No new techniques are proposed on the basis of the work outlined here, but different methods for application of existing procedures are suggested which may enhance their effectiveness.

It should be remembered that as the amount of environmental contamination decreases, the relative importance of transmission by personal contacts apparently becomes more significant. While a great deal of further work is necessary to improve environmental conditions and reduce further the possibility of spread of diarrhea through inadequate excreta disposal and limited water supplies, it will be well to keep in mind that different techniques, many that are simple and easy to apply, may effec-

Table 1. Frequency distribution by families of diarrheal episodes reported and of *Shigella* isolated from residents of Sacaton, Ariz., May 1954 through December 1958

Number of episodes	Number of families	Cumulative number		Positive cultures for <i>Shigella</i>	Number of families	Cumulative number	
		Episodes	Families			Positive cultures	Families

				0-----	39		109

tively decrease the amount of human contact with infectious material.

As the incidence of diarrhea is reduced, homogenous specific foci, which are evident even in areas of high incidence, become increasingly apparent. In any situation a small number of families in the community usually will be responsible for the majority of diarrheal diseases in a particular area. This is illustrated by data from Sacaton and Guadalupe, Ariz., where observations were made from May 1954 through December 1958 and from May 1954 through September 1957, respectively. The prevalence

of *Shigella* among children from 1 to 5 years of age was determined by monthly examination of fecal specimens collected by rectal swab. Data on morbidity experience of the entire population were obtained by monthly interrogation.

Tables 1 and 2 show the frequency with which episodes of diarrhea were reported and the rate of *Shigella* positive cultures in families of the communities. In Sacaton about 57 percent of the cases of diarrhea reported were from only 21 percent of the families. Approximately 62 percent of *Shigella* positive cultures were obtained from 18 percent of the families.

Table 2. Frequency distribution by families of diarrheal episodes reported and of *Shigella* isolated from residents of Guadalupe, Ariz., May 1954 through September 1957

Number of episodes	Number of families	Cumulative number		Number of positive cultures	Number of families	Cumulative number	
		Episodes	Families			Positive cultures	Families
41-----	1	41	1	22-----	1	22	1
33-----	1	77	2	10-----	1	32	2
29-31-----	2	137	4	8-----	2	48	4
21-25-----	12	412	16	6-----	3	66	7
16-20-----	8	555	24	5-----	6	96	13
11-15-----	21	820	45	4-----	12	144	25
6-10-----	55	1,256	100	3-----	25	219	50
5-----	18	1,346	118	2-----	33	285	83
4-----	25	1,446	143	1-----	58	343	141
3-----	26	1,524	169	0-----	155		296
2-----	42	1,608	211				
1-----	78	1,686	289				
0-----	7		296				

Similar patterns were apparent in Guadalupe. Here about 15 percent of the families reported approximately half of the diarrhea and 17 percent of the families provided 64 percent of the positive cultures. The vast majority of families had only a few episodes during the period of study. Obviously, the greatest effect of a community control program could be realized by working with the families having high rates. Programs of environmental sanitation particularly, and to some extent efforts to improve personal hygiene and provide health education, have been directed on a broad base to include all of the population. The same or less effort directed toward the relatively few families or premises that are infected most frequently, and consequently which probably contributed most of the infections, would probably achieve greater reduction in prevalence.

Families responsible for high rates can usually be singled out by public health and social workers after acquiring a superficial knowledge of the community. Further consideration of means for detecting the high rate in families may lead to development of more objective techniques.

The basic concept to emphasize is that regardless of the nature of control measures, it is usually possible to be selective in the places

of their application. The magnitude of the problem may often be discouraging when working with every premise or family in a community, but if the number can be reduced by a factor of 50 to 75 percent, the possibilities of achievement appear more realistic.

Conclusion

Studies on etiology of diarrheal diseases in the Phoenix area have disclosed where further investigations are needed. The importance of additional information on epidemiology and etiology is recognized, but the need is not yet acute. Of more immediate concern, the results reemphasize that more intensive application of available techniques should further reduce morbidity and mortality attributed to diarrheal disease.

Tetanus Therapy

A new method of treating tetanus victims with a curare-like preparation, diplacine, has been developed by Prof. V. N. Shamov of the

Kirov Military Medical Academy, and applied by K. M. Loban, Moscow, and K. A. Nurishchenko, Leningrad, with success. As described by K. Proshunin, treatment in one case consisted of intravenous administration of 60-70 mg. of diplacine to a woman patient, once or twice a day for 10 days. Artificial respiration was provided when necessary. After dosage, opisthotonus disappeared and pain and spasms subsided (24, 91).

Ear Surgery

The gift of hearing to nine children born deaf is reported to result from surgical installation of an artificial eardrum by Professor Malamush of the Dzherzhinskiy Children's Clinic, Moscow (24, 117).

Carcinogens in Cured Meat?

Certain smoke-curing processes in the meat industry in Leningrad introduced materials which, after ingestion, may facilitate cancer formation, according to A. Novikov, director of the Moscow Oncological Institute, quoted in *Magyar nemzet* of Budapest. On the basis of recommendations by Leningrad investigators, he said, the smoke-curing processes were revised (28, 97).

Air Filtration

FP 5 and number 3 membrane filters for removing micro-organisms from the air were compared by Ye. Yu. Zuykova, Moscow. While both were effective, it was concluded that the FP filter is better for rapid filtration of large volumes of air, as it has less resistance to air currents and is less fragile than the membrane filter (28, 102).

Biological Gloves

Protecting skin against solvents and synthetic tars, workers at the Gor'kiy factory, Krasnoye Sormovo, coat their hands with a paste made of 300 grams of casein gum extra, 10 grams of 25 percent ammonia, 300 grams of glycerine, 850 grams of alcohol, and 850 grams of water. The casein is dissolved in half the water, and ammonia in the remaining water, glycerine, and alcohol are added in that order. The paste forms a film on the hands. It washes off with warm water and soap (28, 104).

Brucellosis Vaccine

Tests of a live vaccine against brucellosis are reported from Kazakhstan and Alma-Ata (27, 70).

Decontamination of Leather

A 1 percent salt solution of chloramine in 30 minutes decontaminates hides infected with *Brucella*, without impairing the leather, reports K. Ye. Yedygenov, Alma-Ata (27, 85).

Effects of Exercise

Exertion's effects on bone and muscle were analyzed in a systematic study carried on for 10 years by M. G. Prives, who holds the chair of normal anatomy in the Leningrad medical institute named for Pavlov. Prolonged exertion produces marked changes, especially in the diaphragm. Phosphorus is deposited in the bones that carry the greater physical load, the substantia compacta thicken, and the bone marrow cavities are reduced. If a person changes to an occupation that requires less exertion, the symptoms of hypertrophy decline. The measurements were conducted with the aid of X-ray and radioactive trace elements (27, 82).

Data on Poisons

Toxicological data on certain organophosphorus compounds in relation to their chemical structure have been published by Yu. S. Kagan (26, 82).

Public Health Progress

A book on public health in the U.S.S.R. and achievements of Soviet medicine is reviewed, apparently by CIA, with an effort to summarize the contents of 124 pages. The authors are Nikolay Ivanovich Grashchenkov and Yuriy Pavlovich Lisitsyn. The review says: "It can be gathered from the text that technical changes . . . parallel the development of national economy." The table of contents gives 14 pages to conditions in Czarist times, 25 pages to the October Revolution and its plans for protecting the health of workers, 10 pages to prophylaxis, 14 to an attack on infections, 4 to the prospect of eradicating tuberculosis, 13 to conditioned reflexes, 11 to cardiovascular diseases, 5 to cancer, 3 to blood banks,

4 to new drugs, and 5 to international medical relations. There is no chapter on environmental health services (22, 86).

Soviet authorities have scheduled graduation of 13,700 sanitary physicians, specializing in hygiene and sanitation, for the 5-year period ending 1960. In the previous 5 years, 8,900 were graduated. In the period ending 1965, the number to be graduated will exceed 10,000. It is asserted, "This will satisfy the needs of the Soviet population as far as sanitary epidemic control is concerned." The physicians are trained in 19 sanitary hygiene faculties of medical universities (15, 43).

Public health progress in the Turkmen S.S.R. is the subject of a book by M. G. Berdyklychev, reviewed by P. P. Radkin. He notes that only 20 years ago malaria and trachoma constituted 40 percent of the total incidence of disease in the Republic, whereas these afflictions today are not appreciable. Pappataci fever and typhus have been eradicated (19, 108).

A report on developments in Polish health in the last 15 years has been published by Dr. B. Kozusnik, deputy minister of health, Polish People's Republic (29, 118).

Pasteurella tularensis Strains

Differences in tularemia pathogen strains were analyzed by N. F. Olsuf'yev, O. S. Yemel'yanova, and T. N. Dunayeva, Moscow. The virulent Schu strain, acquired from American investigators in California and Kansas, was compared with virulent strain 503, isolated from *Dermacentor pictus* Herm ticks by N. G. Olsuf'yev in 1949 (28, 92).

Tickborne Encephalitis Virus

Tickborne encephalitis virus was preserved in cow's milk at refrigerator temperatures. In

sour cream and butter, the virus was preserved for 2 months, by M. Gresikova Kohutova, Czechoslovakia (29, 103).

Radiotherapy

A review of medical applications of radio-nuclides in the U.S.S.R. is summarized by Prof. A. Kozlova, Moscow (29, 111).

Antihemorrhagic Drug

Poison from the guersa snake was used to create a drug 10 times as effective in halting bleeding as that derived from the Indian viper, doloja. The drug was developed at the Stalinabad Medical Institute (29, 115).

Carbon 14 in Tobacco Tar

After burning 101 cigarettes, J. R. Chojnowski and A. Dorabalska, in a study conducted in Poland, found that 1 gram of carbon from tobacco tar emitted 154 pulses of radiation a minute. In contrast, carbon from carbon dioxide emitted 95 pulses, and that from carbon monoxide emitted only 62 (20, 71).

Mental Therapy

Properties of a variety of drugs used in psychotherapy are reviewed by Karl Libering, Yugoslavia (20, 90).

Prospects for development of Soviet psychiatry in the next 7 years are described by V. A. Gilyarovskiy, Moscow (19, 106).

Sonic Aerosols

Use of ultrasonic atomizers in the prophylaxis and therapy of diseases requiring aerosol treatment is discussed by A. P. Livenson, Moscow. The bibliography contains seven titles (19, 82).

Fifteen Cents

Nearly 6 million people in Ceylon are protected against malaria at an annual cost of 15 cents per capita. The 1958 report of the antimalaria campaign lists 114 vigilance and subvigilance units and 38 mobile spray units at work. A total of 624 persons are engaged in eradication activities.

Only 27 persons were reported to have died from the disease in 1958, and positive blood smears from fever cases decreased from 6.4 percent of 105,957 smears in 1957 to 1.6 percent of 63,866 smears in 1958.

During the year U.S. Operations Mission in Ceylon contributed supplies, materials, and equipment including 34 jeeps, 7 carriers, and a station wagon to the antimalaria campaign. Dr. L. F. Gunaratna, who joined the campaign in 1946, superintended eradication activities from May 1955 until his death in September 1958. Dr. T. Visvalingham succeeded him as superintendent.

—TROIS E. JOHNSON, M.D., *former chief public health adviser, U.S. Operations Mission, Ceylon.*

Pilot Study in Laos

Last June we started a pilot study to determine the best way to distribute pyrimethamine, a malaria suppressant, to the primitive groups in Laos. Supplies of the drug were given to three voluntary agencies.

The MEDICO clinic at Muong Sing is giving tablets to several hundred persons, including an army detachment nearby. The staff has also sprayed some 70 houses, using the DDT and sprayers supplied by our mission.

The nurse on the International Voluntary Service team at Phlon Savanh is giving the tablets to more than 300 people weekly. She reported that headmen from remote villages are coming to ask for the drug.

The eight clinics run by Operation Brotherhood are supplying pyrimethamine to some 6,000 persons for a 6-month period. Also, the physician for

USOM personnel is giving tablets to 150 villagers and a member of the agriculture department asked for a supply for the staff of the USOM pig farm.

Although the pilot study includes less than 10,000, we expect to gain some valuable information on how to sell malaria prophylaxis and can evolve a workable system for distribution on a larger scale in the future.

Before the pilot study started, antimalarial activities in Laos were strictly a Government function with USOM advice and funding. Now other agencies are eager to participate.

—MANLY B. DONALDSON, M.D., *chief, public health division, and* MAYNARD S. JOHNSON, Ph.D., *malariaologist, U.S. Operations Mission, Laos.*

Resettling Workers

Displaced miners and factory workers from Altiplano mining centers in Bolivia will be settled on farmlands in the tropical highlands of Yungas, 170 kilometers from La Paz. Servicio Cooperativo Interamericano de Salud Pública is cooperating by planning, constructing, equipping, and staffing hospital-health centers in Caranavi, Circuata, and Coroico, which will serve about 25,000 people within 5 years.

—MARCUS P. QUINN, *acting director, Servicio Cooperativo Interamericano de Salud Pública, Bolivia.*

Rehabilitation Teams

The Government of Colombia is sending rehabilitation teams to bolster "all areas of human life" into regions where severe economic and social problems remain as the result of years of political and civil violence.

Following visits to these areas by survey teams and arbiters, the Government made plans to recruit rehabilitation teams. Each will have a physician, nurse, civil engineer, two agricultural extension workers, and a home demonstration agent.

We were asked to help train the teams and are giving them 9 hours of instruction in health education, 1 each in nutrition and industrial health, 2 each in sanitation and public health nursing, and 3 in community organization.

—E. E. MINTY, *acting director, public health division, U.S. Operations Mission, Colombia.*

Federal Publications

A Composite Method for Estimating Postcensal Population of Small Areas by Age, Sex, and Color. *Vital Statistics—Special Reports; Selected Studies*; vol. 47, No. 6, pages 161–185; Aug. 24, 1959; by Donald J. Bogue and Beverly Dunnean.

A comparatively simple, inexpensive technique for preparing specific current local-area estimates sufficiently reliable for most planning and policymaking uses and for studies of population trends is outlined.

The rationale of the method, procedures for making estimates, accuracy of estimates, possible refinements, and indirect estimates are discussed.

The text is supported by nine tables and a line graph.

Maternal Disorders Related to Fetal Stress, Perinatal Death, and Congenital Defects. Selected references, 1952–58. *PHS Publication No. 669 (Public Health Bibliography Series No. 25)*; 1959; compiled by Elizabeth Koenig; 33 pages; 15 cents.

Four hundred and thirteen references to English language studies have been compiled for medical and public health workers interested in the prevention of reproductive wastage.

Infectious diseases are emphasized. Studies on metabolic, neurological, collagen, and blood disorders, drug effects, and statistical data are included.

Municipal and Industrial Waste Facilities, 1957 Inventory. A cooperative State-Federal report. *PHS Publication No. 622*; 1959; vol. 1, 65 cents; vol. 2, \$1.75; vol. 3, \$1; vol. 4, \$1; vol. 5, \$1.75; vol. 6, \$1.25; vol. 7, \$1; vol. 8, 60 cents; vol. 9, \$1.25; the set, \$10.25.

Data of significance in water pollution control programs and waste treatment facilities are segregated into nine volumes according to De-

partment of Health, Education, and Welfare regions. Material in each volume is arranged by State and alphabetically by community. The volume numbers correspond with the region numbers.

Highlights of Research Progress in Allergy and Infectious Diseases, 1958. *PHS Publication No. 694*; 1959; 68 pages; 30 cents.

Significant research accomplishments in intramural and grant-supported projects of the National Institute of Allergy and Infectious Diseases are described briefly. Subject areas include allergy-immunology, virus diseases, cell biology, and parasitic diseases.

Discussions of staphylococcal and cystic fibrosis research, the Middle America Research Unit in Panama, the respiratory virus study in Antarctica, and various special studies are also presented.

Public Health Service Grants and Awards by the National Institutes of Health, Fiscal Year 1959. Health research facilities construction and research grants. *PHS Publication No. 701, part 1*; 1959; 318 pages; \$1.

Grants for health research facilities and for research projects are listed separately by State and institution. A summary table of research grant support by the individual institutes and the Division of General Medical Sciences shows the distribution of grants by State and grantee institutions. The total number and amount of grants to each institution and each State are included in the directory of individual research investigators.

Film Reference Guide for Medicine and Allied Sciences. *PHS Publication No. 487*; 1959; 192 pages; \$1.

Approximately 2,000 up-to-date films and filmstrips produced and in use by agency members of the Interdepartmental Committee on Medical

Training Aids are listed. Also included are productions of civilian agencies or individuals useful to member agencies.

A brief description under each title includes an abstract of the film's content. An alphabetical list of distributors and instructions for borrowing films are provided.

Dental Care in a Group Purchase Plan. A survey of attitudes and utilization at the St. Louis Labor Health Institute. *PHS Publication No. 684*; 1959; 68 pages.

Dental treatment sought from a group clinic by Teamsters' Union members and their families is analyzed in relation to family size, race, income, educational levels, and attitudes toward dental care. The need for dental health education is emphasized.

Poultry Hygiene. Examination and evaluation of poultry and poultry products. *PHS Publication No. 688, part 1 (FDA Technical Bulletin No. 2)*; 1959; 55 pages; 40 cents.

Procedures for antemortem and postmortem inspection of poultry are recommended to officials conducting poultry hygiene programs and as a guide for training lay inspectors and plant personnel.

Included are discussions of 33 diseases and undesirable conditions, significance of specific findings, and disposition of carcasses.

This section carries announcements of new publications prepared by the Public Health Service and of selected publications prepared with Federal support.

Unless otherwise indicated, publications for which prices are quoted are for sale by the Superintendent of Documents, U.S. Government Printing Office, Washington 25, D.C. Orders should be accompanied by cash, check, or money order and should fully identify the publication. Public Health Service publications which do not carry price quotations, as well as single sample copies of those for which prices are shown, can be obtained without charge from the Public Inquiries Branch, Office of Information, Public Health Service, Washington 25, D.C.

The Public Health Service does not supply publications other than its own.

AN EPIDEMIOLOGICAL STUDY OF ENDEMIC TYPHUS (BRILL'S DISEASE) IN THE SOUTHEASTERN UNITED STATES

WITH SPECIAL REFERENCE TO ITS MODE OF TRANSMISSION

By KENNETH F. MAXCY, Passed Assistant Surgeon, United States Public Health Service

At the beginning of this century it was generally held that typhus fever had disappeared from the United States except for an occasional case imported from Europe or from Mexico.¹

In 1910 Dr. Nathan E. Brill (1898, 1910, 1911), of New York, called attention to a typhuslike disease occurring endemically in that city. He hesitated to identify it as typhus because of its generally milder course and its occurrence under circumstances different from those usually associated with that disease. He accordingly believed that he was dealing with a new clinical entity, "an infectious disease of unknown etiology." Cases of this type have since been known in the United States as Brill's disease.

In 1912 Anderson and Goldberger, who had previously reported on the experimental transmission of Mexican typhus ("tabardillo") to monkeys, were similarly successful in the inoculation of a Rhesus monkey with blood from a case of Brill's disease in New York. They found that, as in "tabardillo," one infection rendered monkeys immune to subsequent inoculations of the same passage virus. Furthermore, monkeys previously infected with Mexican typhus were thereafter found immune to Brill's disease, and vice versa. From these observations they concluded that Brill's disease was, in fact, identical with typhus fever, and this conclusion seems to have been quite promptly and generally accepted.

¹ August Hirsch, in his "Geographical and Historical Pathology" (Pub. by the New Sydenham Society, London, 1883), states that:

The proper era of typhus for the United States and Canada begins with the period when immigration from Ireland had set in on a large scale. We thus explain the fact that the ports on the east coast of North America have been the headquarters of the disease, and that the largest contingent of the sick has been supplied by the immigrants themselves, or their countrymen with whom they had come in contact. On the other hand, it is a noteworthy fact that the most careful search among the plentiful epidemiologic records in the literature of the United States fails to discover a single statement as to the occurrence of typhus in the Mississippi Valley or in the Western States, so that the greater part of the continent appears

DECEMBER 24, 1926, pp. 2967-2995

A systematic and thorough account by Dr. Kenneth F. Maxcy of a study of Brill's disease in southern Alabama and Savannah, Ga., confirms its endemic character and points out differences in epidemiological characteristics from those of typhus in the "Old World."

Factors in Diagnosis and Classification of Deaths from CVR Diseases

IWAO M. MORIYAMA, Ph.D.

OVER one-half of the deaths occurring annually in the United States are attributed to cardiovascular-renal diseases (CVR). As may be seen from table 1, the largest frequency of deaths is found in the component arteriosclerotic heart disease including coronary disease. Next in frequency are vascular lesions affecting the central nervous system, and the hypertensive diseases. With the decline in mortality from infectious diseases generally, cardiovascular diseases of infective origin now constitute less than 5 percent of the total CVR disease mortality.

Marked differences in death rates appear for the various demographic characteristics as well as geographic areas. The reasons for these differences are not all clear. Nor is there agreement that the recorded differences are real. Some feel that the problems of diagnosis, reporting, and classification of these diseases are of such a nature that no valid assessment of mortality trends and differentials is possible. Others feel that despite the shortcomings of the data, mortality statistics provide useful indicators of the general trend and magnitude of CVR disease mortality. This disagreement is rooted in the lack of quantitative information with respect to these problems.

Various factors complicate the interpretation of CVR disease mortality statistics. First, there is the question of the reliability of the

diagnostic data on which the medical certification of causes of death is based. There are several facets to this problem. The prevailing concept of disease and diagnostic criteria of the day provide the background for medical practice. The amount and quality of diagnostic evidence available to the medical certifier, and the diagnostic acumen of the attending physician determine the quality of diagnosis made. At this point, it should be recognized that diagnoses are judgments arrived at after a study of available clinical and pathological observations. Even with standard diagnostic criteria, it is highly unlikely that absolute accuracy in diagnosis will ever be possible for diseases of the CVR system because of the varying medical backgrounds and experience of the relatively large population of physicians.

There can be no question that over the years there has been a great increase in knowledge with resultant changes in the concept of cardiovascular-renal diseases. The development of diagnostic criteria and techniques and improvements in diagnostic facilities and methods have undoubtedly influenced cardiovascular-renal disease mortality statistics. For example, the diseases of coronary arteries which today are the most important component of the CVR disease complex were not reported with any great frequency as a cause of death until about 1926. Halsey, cited by Hedley (1) and Atkinson (2), has pointed out that there has been a change in emphasis in the diagnosis of heart disease away from valvular to myocardial diseases and more particularly to the coronary vessels which supply the myocardium. Levy's review (3) of the clinical and pathological rec-

Dr. Moriyama is chief, Mortality Analysis Section, National Office of Vital Statistics, Public Health Service. This paper was prepared for presentation at the annual meeting of the American Statistical Association in December 1958, Chicago, Ill.

Table 1. Number of deaths and death rates for the components of major cardiovascular-renal diseases, United States, 1956

Major cardiovascular-renal diseases	Number of deaths	Rate ¹	Percent
Total.....	854, 152	510. 7	100. 0
Vascular lesions affecting central nervous system.....	177, 845	106. 3	20. 8

Other cardiovascular-renal diseases.....	61, 331	17. 5	7. 2

¹ Rate per 100,000 estimated population.

ords of the New York Presbyterian Hospital for the period of 1920 to 1930 showed that although the incidence of coronary disease in the pathological records was fairly constant each year (10 to 12 percent) throughout the decade, there was an increase of 400 percent in the frequency of clinical diagnosis of various forms of coronary diseases. Levy states that "It was after the publication of the papers of Herrick in 1912 and again in 1919 that interest of the profession in this country was aroused in the problems of acute coronary obstruction, and in the succeeding years clinicians became more alert in recognizing the disturbance in the coronary circulation and recorded them more frequently."

Other significant changes in the concept of CVR diseases relate to the vascular changes caused by diabetes (4) and the possible etiological relationship between cholesterol and atherosclerosis. The role of hypertension and the effects of therapeutic procedures on hypertensives are beginning to be better understood. These developments have an impact upon the diagnosis of CVR diseases, but it is not possible to determine the extent to which the statistics on CVR disease mortality are influenced. Undoubtedly, however, data on the individual components of the CVR disease complex are significantly affected. On the other hand, most of the shifts are within the CVR system, and

mortality data for all CVR diseases are probably relatively free from complications resulting from these changes in concept.

A number of studies have explored the accuracy of cause-of-death statements on death certificates (5-7). On the basis of comparisons between clinical and pathological records, the diagnostic statements relating to CVR diseases have been found in these studies to be relatively poor. Those investigations which utilize autopsy findings as the standard of reference have serious limitations. For example, diagnoses of clinical entities cannot always be established by autopsy findings. In the study of James and associates (7), the use of autopsy data decreased the proportion of deaths attributed to such causes as diabetes and hypertensive diseases and increased the proportion attributable to arteriosclerosis.

Deaths of patients in hospitals tend to be weighted with surgical cases, acute illnesses, and diseases and conditions relatively difficult to diagnose. Pathological findings are sought more often for deaths where the clinical diagnosis is not clear or where diagnostic confirmation is desired. Thus, the selection of deaths in hospitals, particularly deaths for which autopsies were performed, should lead to greater disagreement than would appear in a hypothetical situation where cause-of-death statements are compared with clinical or pathological findings.

Pennsylvania Study

In order to avoid the selective factors involved in the study of hospital deaths that come to autopsy, the medical certifier was queried in a sample of death certificates issued in hospitals for a 3-month period in 1956 in Pennsylvania. The methodology and results of this study were published recently (8). Briefly, the method of study was to send a questionnaire to the physician signing the death certificate asking for information on diagnostic methods, the pertinent findings on which the medical certification of death was based, and an expression of his certainty of the diagnosis on the medical certification. The returns were reviewed by an internist and rated as to quality (type and amount) of supporting

Table 2. Quality (type and amount) of supporting diagnostic information on cardiovascular-renal diseases, Pennsylvania mortality sample, 3-month period, 1956¹

Major cardiovascular-renal diseases	Total number	Percent			
		Very good	Good	Sketchy	No report
Total.....	1, 406	28. 7	19. 8	47. 4	4. 1
Intracranial lesions of central nervous system.....	254	20. 9	23. 2	51. 2	4. 7

Other cardiovascular-renal diseases.....	102	45. 1	21. 6	29. 4	3. 9

¹ Totals adjusted to number of deaths in current mortality sample.

diagnostic information and consistency of medical certification with the diagnostic evidence. Also, the reviewing internist rated his impression of certainty of the diagnosis.

The findings on CVR diseases may be summarized as follows:

1. A relatively large proportion (47 percent) of the available diagnostic information on CVR diseases was sketchy (table 2); in 20 percent, it was "good;" and in 29 percent, "very good." In 4 percent, there were no returns on which to make an assessment.

2. Analysis of evidence presented in 1,406 deaths in support of a diagnosis of the major CVR diseases judged the certified diagnosis most probable in 78 percent of the deaths, an-

other diagnosis equally probable in 14 percent, and a different diagnosis preferred in 3 percent (table 3). No diagnostic information was available in the remaining 4 percent. These figures may to some degree understate the quality of medical certifications of deaths from CVR diseases since judgments were made on the specific diagnoses reported. Some classified as "another diagnosis equally probable" or "another diagnosis preferred" could well have been the "most probable diagnosis" had the cause-of-death statement referred to another related disease within the cardiovascular-renal system. With respect to the specific diagnoses, the proportion of medical certifications judged to be the "most probable diagnosis" ranged from 67

Table 3. Consistency of medical certification with diagnostic evidence on cardiovascular-renal diseases, Pennsylvania mortality sample, 3-month period, 1956¹

Major cardiovascular-renal diseases	Total number	Percent			
		Most probable diagnosis	Another diagnosis equally probable	Another diagnosis preferred	No diagnostic information
Total.....	1, 406	78. 2	14. 4	3. 3	4. 1
Vascular lesions of central nervous system.....	254	85. 0	8. 7	1. 6	4. 7
Rheumatic fever and rheumatic heart disease.....	41	82. 9	9. 8	0	7. 3
Arteriosclerotic heart disease including coronary diseases.....	692	78. 6	16. 5	1. 3	3. 6
Other heart diseases, except hypertensive.....	167	66. 5	19. 8	11. 4	2. 3
Hypertensive diseases.....	150	76. 0	16. 0	2. 0	6. 0
Other cardiovascular-renal diseases.....	102	78. 4	5. 9	11. 8	3. 9

¹ Totals adjusted to number of deaths in current mortality sample.

percent for "other heart diseases, except hypertensive" to 85 percent for the vascular lesions affecting the central nervous system.

3. The reviewer's evaluation of the diagnostic information on deaths certified by physicians indicated that diagnosis was solidly established in 33 percent of the CVR deaths, and reasonably well established in 47 percent of the deaths (table 4). In other words, in 80 percent of the deaths from CVR diseases, the diagnoses were evaluated to be reasonable or better. There was more uncertainty concerning the accuracy of diagnoses of deaths from hypertensive diseases and the residual group of CVR diseases. The query form was probably weakest in eliciting clinical evidence which, in part, may account for the lower proportion of solidly established and reasonable diagnoses for these rubrics.

4. A relatively large proportion (15 percent) of deaths from CVR diseases in Pennsylvania was certified by the medical examiner or coroners. This proportion was much higher (31 percent) for coronary heart disease, which is frequently linked with sudden death. The care with which the medical examiner and coroners discharge their legal responsibilities can significantly affect statistics for CVR disease mortality. In Pennsylvania, at least, the coroners or medical examiner often consult the family physician, if there is one, before making out the medical certificate, or, if the reasons for death seem unclear, an autopsy is ordered.

5. The differences in diagnostic quality do

not appear to be important factors in the interpretation of sex and age differentials, in the more usual situation where the interest is in reasonable diagnosis or better.

6. Data by place of residence of the decedent showed slight differences by population size; but these do not seem large enough to account for much of the observed urban-rural differences in mortality.

7. There seemed to be a marked urban-rural difference in the quality of diagnoses according to the physician's place of practice. About 80 percent of the diagnoses of urban medical practitioners were rated as "solidly established" or "reasonable," while 70 percent of the diagnoses of their rural colleagues fell into those categories.

The establishment of an adequate diagnosis is important, but for the purposes of mortality statistics, diagnostic information must also be reported properly on the death certificate. This requires a complete statement of the judgment of the medical certifier on the sequence of events leading to death, in unambiguous medical terminology. Unless all of the pertinent facts are reported completely in the proper sequence, accurate and consistent classification becomes difficult.

In the Pennsylvania study, the diagnostic information on CVR diseases was reported "completely" by physicians on 84.7 percent of the death certificates (table 5). On 11.8 percent, the medical certification was incomplete in some respects. For example, an intervening

Table 4. Reviewers' evaluation of diagnostic information on cardiovascular-renal deaths certified by physicians, Pennsylvania mortality sample, 3-month period, 1956¹

cause in the sequence of events was omitted. A few, 1.9 percent, were grossly incomplete. On 1.6 percent, the diagnostic information was judged to be reported incorrectly. As might be expected, the proportion of medical certificates completely reported by the medical examiner and coroners was lower (70.4 percent). However, the proportion adjudged grossly incomplete and incorrect did not differ significantly from that for reports by private physicians.

The reporting of sequence of events was

generally good, despite the difficulties involved in determining the relationship between the various components of CVR diseases. As may be seen in table 6, about 94 percent of the certifications of CVR diseases by physicians represented correct or substantially correct sequence. The terminology used was also generally good, except in the group categorized as "other diseases of the heart, except hypertensive." Here the persistent use of the obsolete term "chronic myocarditis" resulted in a high proportion of reports by certifying

Table 6. Percent of cardiovascular-renal disease reported by physicians in proper sequence of events using good or bad terminology, Pennsylvania mortality sample, 3-month period, 1956¹

physicians being cited by the reviewer as poor terminology. In Pennsylvania, the reporting of CVR diseases by medical examiner and coroners does not appear to present much of a problem. This may not be the case in other parts of the country.

The medical certifier provides the information which forms the basis of cause-of-death statistics. For statistical purposes this information is classified according to certain prescribed rules, by the current categories of the International Lists of Diseases and Causes of Death. For primary mortality tabulations, it is necessary to select a single cause which is presumably the disease or condition which initiated the train of events leading to death. In CVR diseases, the cause so selected is frequently modified by the special provisions in the classification. Thus, data on certain presumptive etiological factors are lost. For example, "cerebral hemorrhage due to hypertension" is classified as intracranial lesions of vascular origin, and the presence of hypertension does not appear in the tabulations.

The problems of classification have been described elsewhere (9-13). Aside from the difficulties in adequately characterizing the diseases of the CVR system by selecting a single underlying cause, the decennial revisions of the international lists limit severely the compilation of a comparable series of statistics for the specific components of the CVR diseases. However, in view of the fact that revisions of the classification generally entail further subdivisions of CVR diseases and transfers within the CVR system, comparability of statistics for all CVR diseases has not been affected materially over the years.

Conclusions

The situation with respect to the interpretation of CVR disease mortality statistics in the United States appears to be as follows:

1. Available data on the accuracy of diagnosis and of medical returns on death certificates are fragmentary and have certain limitations. The relative dearth of good supporting diagnostic information appears to be a problem in CVR mortality, but the Penn-

sylvania study suggests that the quality of diagnosis as reported on death certificates is for the most part reasonably good or better.

2. The universal adoption of diagnostic criteria such as those of the New York Heart Association (14) would materially improve the diagnostic information on death certificates. However, absolute and unfailing accuracy of diagnoses is unattainable. The etiological and pathological relationships in CVR diseases are often complex, and there is little opportunity for the medical certifier to make a thorough antemortem examination in a large proportion of deaths, say from coronary disease, because the patient dies suddenly.

3. Despite the various shortcomings of mortality data for the specific components of CVR diseases, data for the total complex of CVR diseases appear reliable for interpretation of mortality trends. More information is needed on a national scale and further work should be done to explore the factors of geographic distribution.

4. Because of the periodic revisions in classification, the study of the course of mortality of the components of CVR diseases will have to be limited necessarily to short-run analyses.

5. There should be a more general recognition that mortality data are not precise measures, but that in epidemiological studies they are useful in suggesting leads to be elaborated by other study approaches.

6. Preparatory work is now underway for the 8th revision of the International Lists of Diseases and Causes of Death. It is expected that the classification will provide for a greater number of disease complexes in the section on diseases of the CVR system. This will eliminate some of the troublesome factors in satisfactorily characterizing CVR diseases now encountered in primary mortality tabulations. However, it will not be possible to identify all the significant relationships. For this purpose, there will be a need for multiple-cause tabulations.

7. There has been a growing interest in studies of CVR disease mortality on an international scale involving various ethnic groups, in order to identify some of the etiological factors. A study group of the World Health

Organization is now developing diagnostic criteria for international use. Continuing interest in this area should be helpful in improving CVR disease mortality statistics.

World Health Day, April 7

The theme of World Health Day 1960, observed each year on April 7, is "Malaria Eradication—A World Challenge."

The Public Health Service will supply, upon request, program materials and background information on the World Health Organization, the history and current status of malaria throughout the world, and the progress which has been made in the worldwide malaria eradication effort. The Public Health Service also has an International Health Speakers' Bureau which includes prominent individuals throughout the United States who have been active in international health affairs and who have indicated their willingness to speak on World Health Day programs.

Requests for this material, or for other specific information about international health organizations or United States participation in international health programs, should be directed to the Assistant to the Surgeon General for International Health, U.S. Public Health Service, Department of Health, Education, and Welfare, Washington 25, D.C.

April 7 is the anniversary of the day on which the World Health Organization came into being. WHO, established in 1948, is one of the specialized agencies of the United Nations, with membership of 90 countries.

Assay of Tests for Syphilis on Unheated Serum

HILFRED N. BOSSAK, B.S., WILLIAM P. DUNCAN, B.S., AD HARRIS, and VIRGINIA H. FALCONE, B.S.

A METHOD for testing unheated serum in the same manner as plasma in the rapid plasma reagin (RPR) test (1) has recently been reported in which the comparative results obtained with this method and several other procedures on specimens from a serologic survey conducted in North Carolina, are described (2). An earlier method employing measured amounts of unheated serum and RPR antigen suspension, and referred to as the unheated serum reagin (USR) test, was included among the nontreponemal tests performed in the SERA study (3).

The establishment of a serum bank of clinically categorized donors at this laboratory has been previously described (4). Its availability has made possible the rapid assay of newly published procedures, and it has again been used in this study.

This report presents the comparative results obtained with the two procedures performed on unheated serum and the VDRL slide test on serums from medically defined patient groups.

Materials and Methods

The rapid plasma reagin test on unheated serum (RPR-US) was performed in exactly the same manner as the RPR test (1) except that serum was substituted for plasma.

The unheated serum reagin test was per-

formed according to the technique described in the SERA study (3).

The VDRL slide test was performed in accordance with the technique described in the Manual of Serologic Tests for Syphilis, 1959 revision.

All tests were performed at the Venereal Disease Research Laboratory, Chamblee, Ga. VDRL slide test results on those serums that were included in both the SERA study and the serum bank were taken from the SERA study report. The two tests on unheated serum were run on all the specimens at a later date. VDRL slide tests were performed at the same time on any specimens added to the bank which had not been included in the SERA study.

The donors of the serums tested were in the following categories:

PRESUMED NONSYPHILITIC

- Apparently healthy donors presumably with no history of previous or present infection with syphilis.

SYPHILIS

- Donors with primary syphilis proved by darkfield examination, who had not received treatment.

- Patients having had primary syphilis proved by darkfield examination and who had adequate treatment with 2,400,000 units or more of penicillin not less than 2 nor more than 4 years prior to time blood was taken.

- Donors with secondary syphilis proved by darkfield examination, who had not been treated.

Mr. Bossak, Mr. Duncan, and Mrs. Falcone are bacteriologists with the Venereal Disease Research Laboratory, Communicable Disease Center, Chamblee, Ga., of which Mr. Harris is director. (Manuscript received for publication September 25, 1959.)

• Patients with secondary syphilis proved by darkfield examination who had adequate treatment with 2,400,000 units or more of penicillin not less than 2 nor more than 4 years prior to time blood was taken.

• Donors with either latent or late syphilis, adequately treated with 4,800,000 units or more of penicillin.

WITH CONDITIONS OTHER THAN SYPHILIS

• Hospital patients with a variety of diseases or conditions, not receiving antibiotics and having no history of clinical evidence of syphilis; patients 12 years of age or younger with yaws; patients with pinta, below age at which associated syphilis might be expected; and leprosy patients not thought to have associated syphilis.

BIOLOGIC FALSE POSITIVES (BFP)

• Patients with reactive nontreponemal tests, at least one nonreactive (TPI) *Treponema pallidum* immobilization test, and no clinical evidence of syphilis.

• Patients with reactive nontreponemal tests, no previous TPI test, and no clinical evidence of syphilis.

Results

The results obtained with the three procedures on 592 serums from presumed nonsyphilitic persons are shown in table 1. Of the total number of serums tested, 329 were residuals of SERA study specimens which had not been previously heated or tested and had been stored in the frozen state in tightly sealed containers since the original date of collection and separation of the serum. The remaining 263 specimens were obtained from other sources and were added to the serum bank at later dates. Regardless of the origin of the serums, however, absolute agreement was obtained with the unheated serum reagin and the rapid plasma reagin test on unheated serum. Percentage reactivity was identical with all three tests (0.34 percent), although the two serums which reacted in the tests with unheated serum were not the same serums that were reactive in the VDRL slide test. The *Treponema pallidum* immobilization test, performed in this laboratory on these four specimens, was reactive in each instance, suggesting a treponemal infection, past or present.

Table 2 lists the results obtained in six clinical

Table 1. Results with 592 serums from presumed nonsyphilitic persons

Test	Nonreactive		Reactive ¹		Total	
	Number	Percent	Number	Percent	Number	Percent
Unheated serum reagin.....	590	99.66	2	0.34	592	100
Rapid plasma reagin on unheated serum.....	590	99.66	2	.34	592	100
VDRL slide.....	590	99.66	2	.34	592	100

¹ Reactive plus weakly reactive.

Table 2. Reactivity rate ¹ in six clinically defined categories of syphilis

Category	Number of specimens	USR test		RPR-US test		VDRL slide test	
		Number	Percent	Number	Percent	Number	Percent
Primary, untreated.....	119	85	71.4	86	72.3	79	66.4
Primary, treated.....	29	4	13.8	4	13.8	0	0
Secondary, untreated.....	98	98	100.0	98	100.0	98	100.0
Secondary, treated.....	18	8	44.4	8	44.4	5	27.8
Latent, treated.....	25	23	92.0	23	92.0	17	68.0
Late, treated.....	203	190	93.6	191	94.1	178	87.7

¹ Reactive plus weakly reactive.

Table 3. Reactivity rate¹ in conditions or diseases other than syphilis

Category	Number of specimens	USR test		RPR-US test		VDRL slide test	
		Number	Percent	Number	Percent	Number	Percent
Conditions other than syphilis.....	73	7	9.6	7	9.6	4	5.5
Biologic false positive, nonreactive TPI test.....	111	53	47.7	53	47.7	54	48.6
Biologic false positive, no TPI test.....	109	55	50.5	55	50.5	48	44.0

¹ Reactive plus weakly reactive.

cally defined syphilis categories. Little difference was noted in the reactivity rate of the two tests on unheated serum although the RPR test appeared to be slightly more reactive than the procedure using measured amounts of reagents. Both tests were more reactive than the VDRL slide test in all categories except untreated secondary syphilis. In adequately treated primary, secondary, and latent syphilis, the lower reactivity rate of the VDRL slide test was most apparent, suggesting a more rapid reversion to nonreactivity after treatment.

Findings with the three procedures in conditions or diseases other than syphilis are summarized in table 3. With conditions other than syphilis the incidence of reactivity with the two tests on unheated serum was approximately twice that of the VDRL slide test. Results obtained with all three tests were approximately the same in one biologic false positive category, composed of serums from persons who had been screened with at least one nonreactive TPI test. None of the patients in the second BFP category had been previously tested with the TPI. In this group, the VDRL slide test was less reactive than the two procedures performed on unheated serum.

Summary and Conclusions

The comparative results obtained with the unheated serum reagin test, the rapid plasma reagin test on unheated serum, and the VDRL slide test on serums from medically defined patient categories are presented.

1. No significant differences were observed between the two tests on unheated serum.

2. Percentage reactivity was the same with all three procedures in the group of healthy, presumably nonsyphilitic persons.

3. In serums from donors with syphilis, the two procedures with unheated serum were more reactive than the VDRL slide test in all categories except secondary, untreated, including those patient groups who had received adequate treatment.

4. The unheated serum reagin test and the rapid plasma reagin test on unheated serum were almost twice as reactive as the VDRL slide test in the category of patients with diseases other than syphilis.

5. The results obtained with the three procedures were quite similar in the two groups of patients classified as biologic false positive reactors.

APHA

*Conference
Report*

SUMMARIES OF SELECTED PAPERS
from the 87th annual meeting
of the
AMERICAN PUBLIC HEALTH ASSOCIATION
and related organizations
held at Atlantic City, N.J.
October 19-23, 1959

THE CONFERENCE REPORT

With the assistance and cooperation of the authors, the staff of *Public Health Reports* has summarized roughly four-score papers presented at the 87th annual meeting of the American Public Health Association and related organizations, in Atlantic City, October 19-23, 1959.

The objectives of this annual summation are to touch bases for the members of the conference who found it physically impossible to make the rounds of every meeting in which they were interested; to present in a single package many of the major topics presented at the conference; to permit those unable to attend the conference to obtain a wide-screen view of developments in public health work; and to provide authors of papers with an opportunity to reach a broad professional audience, with at least a summary of their information, in anticipation of the usual course of publication.

This summation has been a bit more eclectic than usual. As the American Public Health Association plans to publish in three separate supplements to its journal papers presented by foreign guests of the conference, papers on heart disease, and papers dealing with behavioral sciences, few if any of those papers are represented here.

Certain other papers were passed by because they did not lend themselves to treatment in this collection, or because they are now in print in full. Many interesting talks given at the conference are not carried here because the authors either spoke without reference to a text or did not provide copy for *Public Health Reports*.

This summation is prepared at the invitation of the American Public Health Association. For further details on the papers touched upon, readers are advised to communicate with the authors. Many of the papers presented to the conference, whether or not they are mentioned here, remain under consideration for full publication in professional journals in the near future.

The next annual conference is scheduled for October 31 to November 4, 1960, in San Francisco.

Public Health Trends . . .

Mene Mene Tekel Ufarsin Decoded

A willingness to meet the inevitable halfway was recommended by Elton D. Woolpert, assistant to the Surgeon General, Public Health Service, as the appropriate response to changes portended by the modern handwriting on the wall which he discerned in statistics of social trends.

Predicting a high rate of obsolescence of plans to meet the future, he advocated anticipating imminent changes with new methods, well tested and thoroughly developed by public health research and demonstration. The alternative he left to the imagination.

Among emerging stresses which are on the point of producing intolerable social strains, he mentioned the following:

Personnel needs: The demand for physicians alone, he asserted, calls for founding at least one new medical school a year for the next 15 or 20 years, if only to keep the present proportion of medical services.

Facilities: The number of beds and other accommodations needed to provide for the aged and chronically ill is not keeping pace with the increase of the aged population.

Government: Local governmental structures of the past are ill-suited to the management of urban complexes, with their interrelated systems of recreation, education, medical care, transportation, water supply, and waste disposal.

Services: Present jurisdictional lines are ill-suited to administering related public services. What is needed is "not so much new boxes on the organization charts" as new patterns of services meaningful to the public.

Taxation: Dependence on property taxes, inadequate assessment of real property taxes, and rigid tax and debt limit are serious obstacles to adjustment of public service and construction programs to meet needs of a growing population in a period of rising prices.

Urban representation: With State legislatures elected to serve a population pattern of 1900, rather than the dominantly urban pattern of the present, municipal officials, hampered also by limits on powers to tax or incur debt, are obliged to seek direct assistance from the Federal Government for community services.

Research: Public health administration, facing new challenges with the encumbrance of archaic and impoverished institutions and methods, lags notably in obtaining studies which will appraise its needs and which may devise methods of adjusting present facilities or creating new approaches.

In conclusion, Woolpert observed that his efforts at translating the handwriting on the wall were by no means complete, that others for years to come will have the pleasure of continuing in that occupation.

Private Physicians Aid City Services

Foreign visitors to the APHA conference, so accustomed to governmental management of health services that they can hardly conceive of private support of public health facilities, went through a mental earthquake as they heard a description by Dr. Harry S. Lichtman and Simon Podair of the work of the public health committee of the medical society of the County of Kings, New York City. Dr. Lichtman is chairman of the committee.

Members of the committee include general practitioners and many specialists, including the authors of the report, both employed by the New York City Department of Health. Lichtman is borough chief of Brooklyn in the bureau of preventable diseases, and Podair is coordinator of health education for the borough. Nonmedical specialists are invited to sit with the committee as consultants.

In 1956, the committee threw its full resources into a drive for Salk vaccine inoculations against poliomyelitis in parochial schools and

child care centers. This program broadened into a drive for mass immunization of adults, which entailed free services by members of the medical society, using vaccine contributed by tax-supported agencies.

A second effort of the committee has been directed at enlisting the efforts of private physicians in improving public knowledge and attitudes toward questions of health, through private conversations with patients. The committee supplies physicians with information on developments in health matters of public interest and encourages physicians to supply patients with effective answers to quackery, sensationalism, superstition, and misinformation.

One device for encouraging the transmission of such information has been a series of public forums called "Twelve Wednesdays for Your Health." Although only 400 are seated in the lecture hall where the issues are discussed, the program is publicized to 15,000 members of the institute, and the proceedings are reported in the New York press.

Voluntary associations collaborate in these forums, to the extent they are directly concerned. They put up exhibits, supply literature, and offer information on the spot.

Some of the lectures given at these meetings have been published in the *New York State Journal of Medicine*, although they were prepared originally for information to a lay audience.

The success with the forums led to a radio program for a local audience, which has since been transcribed and broadcast by the Voice of America. The series of radio interviews has been taped and rebroadcast by the station, WEVD.

Because of controversies on public health procedures, initiated by cultists, the committee arranged with newspaper publishers to prepare answers to attacks on fluoridation, poliomyelitis immunization, and other public health programs. It has also prepared a weekly health column for publication in the Brooklyn press.

A speakers' bureau was organized by the committee in response to a great demand for qualified speak-

ers from parent-teacher associations, churches, centers for the aged, settlement houses, and other institutions. A panel was organized by the committee from members of the medical society. Names are forwarded when requests are made by either community organizations or the health department. The services of the speaker are reported in the bulletin of the medical society.

A subcommittee on mental health has been organized. One of its prime objectives is to improve the psychiatric training of the non-psychiatric physician. In cooperation with the Kings County chapter of the American Academy of General Practice, seminars are conducted under direction of one psychiatrist, with six to eight participating physicians. The method has been so well received that several hospitals are experimenting with it for postgraduate training. In December 1959 the U.S. Public Health Service gave the subcommittee on mental health a grant of \$51,840 for 3 years, for the education of the nonpsychiatric physician.

Periodic physical examinations of physicians were organized by the committee, utilizing facilities of four civic health centers in Brooklyn. More than 200 physicians have been examined.

A recommendation of the committee, urging footprints of infants and fingerprints of mothers for purposes of identification, has become a requirement of the New York City Health Code.

A directory of medical and social services which physicians may use in counseling patients is the latest project of the committee.

The committee has also prepared and released more than 12 reports on issues of public health significance, such as employment of hospital epidemiologists.

Land Competition Becomes Planned

The ancient competition for land, once a simple preoccupation of militant farmers, hunters, trappers, cat-

lemen, sheepherders, miners, merchants, and robber barons, has become refined. As described by B. Budd Chavooshian, chief of the New Jersey State Planning Bureau, the hurlyburly of the battlefield has settled down to a spell of fretting at the drawing board, murmuring at conference tables, and activity at the polls.

Land uses for each individual, neighborhood, and business have become so complex and interrelated that internal conflicts, according to Chavooshian, have virtually imposed upon entire regions demands for planned land use which frequently become issues for political action.

Planning for land use, as he describes it, consists of preparing reports, maps, and charts describing present and prospective uses of land in relation to needs; designing effective means for moving freight and passengers; and assuring space for recreation, educational facilities, and public utilities.

Private interests in land use are classified by planners into residential, commercial, and industrial users, each with special requirements as to location and facilities. He recommended also that land-use plans pay regard also to the conversion of land for agriculture, in view of the fact that builders of roads, housing, industrial plants, and other urban facilities are gobbling up 3,000 additional acres of open land every day.

Instruments of executing land plans mentioned by Chavooshian, apart from such traditional means as credit, include zoning and building regulations, ordinances regulating subdivisions, and urban renewal programs supported by Federal funds.

As examples of communities which have serious planning programs underway, Chavooshian briefly mentioned Toronto, Canada, Dade County (Miami), Detroit, and the Twin Cities of Minnesota, Minneapolis and St. Paul.

The State Planning Bureau in New Jersey, he said, is one of the few agencies to set up planning services for a long list of communities. Mas-

ter plans for 60 of 120 communities receiving these services have been completed with regard to needs of adjacent areas, and plans for 15 others were nearly completed last fall. Over 40 additional municipalities have applied for similar planning assistance. This program is undertaken under the provisions of section 701 of the Federal Housing Act of 1954, as amended. The agency also has an urban renewal survey underway in 278 municipalities comprising 9 counties in the northeastern portion of the State. This survey is financed in part by the Federal Government under the provisions of section 314 of the Housing Act of 1954.

In meeting the problem of land development, the bureau has also initiated a broad base State planning program, including capital improvements programming.

The Doctor's Dilemma: Panic or Prevention

As one more piece of historical evidence, the case of the fresh flounder tainted with sodium nitrite was reported by Dr. Morris A. Shiffman, Dr. Milton Werriu, and Dr. Sylvan Fish, of the Philadelphia Department of Health, to illustrate the delicate task of a health department in protecting the public without wreaking havoc. The authors are chiefs, respectively, of milk and food, veterinary public health, and communicable disease sections of the department.

The flounder outbreak struck shortly before Good Friday last year. With one child dead from sodium nitrite poisoning, the department took emergency measures to detect the source, alert the public, and recall shipments which might have affected as many as 4,000 persons. The preventive action was on the whole successful. At the same time, hundreds sought medical aid unnecessarily; unknown quantities of harmless fish were discarded; and sales of seafood in Philadelphia, dropping immediately to 10 percent

of normal, did not recover completely for several months.

Within 20 hours after receiving the first word that a family had suffered food poisoning, originally thought to be botulism, the Philadelphia Health Department, the New Jersey State Health Department, and the New Jersey State Police, and the Food and Drug Administration had determined that an unknown quantity of flounder containing sodium nitrite had been distributed in the area. The time was shortly before the dinner hour, barely enough to meet the 5 o'clock deadline of the evening papers.

Under the circumstances, say the authors of the report, there was no time for preparing "a carefully worded press release." Newspapers and radio stations were notified orally by the press officer of the department. That night, one headline read, POISON FISH FLOODS AREA. TV and radio programs were interrupted to issue warnings which were repeated at 15-minute intervals. Later, these media announced antidotes, recommended by the Philadelphia Health Department for those who experienced symptoms of poisoning following a meal of flounder.

Meanwhile, the source of contaminated flounder had been identified. Police on foot and in radio cars carried warnings to all possible distributors. In suburban and rural areas, police broadcast warnings by loudspeaker. They also put out an announcement on a 14-State teletype network, reaching well outside the market area, to the distress of adjacent distributors of seafood.

The public response may be judged by the fact that the municipal switchboard handled 20,000 calls on the night of the alert. Additional thousands of calls were directed to hospitals and physicians. At the health department office, these calls were answered by reading of a prepared statement by operators who stayed on duty far beyond the normal working period.

Reflecting on these events, the authors are uncertain that the an-

nouncement could have been issued with a greater degree of discretion. The nature of the news itself, they feel, more or less determined its treatment and the public response.

Although Philadelphia Health Department officials are in 24-hour contact with the municipal radio dispatcher for emergency calls, and although the department has a poison control center operating 24 hours a day, the officials feel it might be desirable to have a 24-hour emergency service in the department, with one trained person on hand at all times to issue information and direct emergency actions.

State Consultation Raises Hospital Standards

A hospital consultation program in a State health department can provide many varied services to hospitals and help assure the best possible quality of patient care, according to Dr. Goldie B. Corneliussen, director of the maternal and child health division, and Dr. Fanny H. Kenyon, chief of the hospital consultation and licensing section, Michigan Department of Health.

Such a program, they pointed out, requires teamwork of the highest order, and matre personnel who will learn as well as teach. Consultation services are usually given by a relatively small team assigned full time to the hospital program, supplemented, as needed, by specialists such as epidemiologists, pediatricians, and obstetricians, laboratory scientists, dietitians, ventilation and radiological engineers, and statisticians, whose responsibilities include but are not limited to service to hospitals.

The Michigan consultation team is directed by a physician, and includes four nursing consultants, two part-time sanitary engineers, and two clerks. Corneliussen and Kenyon stressed the importance of medical direction of the program, pointing out that a physician-director, preferably one with experience in private practice as well as public

health, has both understanding of patient care and hospital problems and status with hospital administrators and staff. All the Michigan nursing consultants have had hospital supervisory experience and each has a master's degree in a different nursing specialty.

Michigan gives consultation to more than 260 hospitals and also to State mental hospitals and tuberculosis sanatoriums. Consultation is provided on such diverse matters as layouts of nurseries, maternity departments and kitchens, problems of central supply ventilation, help in developing obstetrical policies, educational programs, record forms, and the establishment of procedures and routines for brand new hospitals.

Aid is given also in emergencies. In cases of infection in a hospital, the department's epidemiologist heads the study team and has top priority on services of nursing consultants and sanitary engineers. When the infection is in a newborn nursery, the nursing consultant dons her uniform and often spends several days observing techniques on all shifts.

Licensing Responsibilities

In 1951, the responsibility for licensing hospitals with maternity departments was transferred to the Michigan Health Department from the Department of Welfare. The consultation staff was somewhat fearful, according to Corneliussen and Kenyon, that the new licensing operation might interfere with the excellent relationships it had established with hospitals. Instead, the licensing function has seemed to strengthen the consultation program and the department's years of experience with consultation have helped to play down the "policing from above" too often inherent in licensing programs, they reported.

With the assistance of hospital administrators, physicians, and nurses, the State developed higher hospital standards than it had originally thought feasible, Corneliussen and Kenyon stated. Only hospitals

approved and certified by the State health commissioner are eligible to receive payment for the care of public assistance recipients from Federal, State, and local funds.

Hospitals were given a reasonable time to comply with the regulations, with the health department providing advice and consultation on methods of meeting the requirements efficiently, economically, and practically.

Michigan's "Rules and Minimum Standards for Hospitals" now include 180 individual regulations, divided into three categories: those requiring immediate compliance, those requiring planned compliance, and a third group of undesignated rules which are to be placed in the immediate and planned categories at dates considered reasonable for the majority of hospitals.

In 1951, the first year of licensing, hospitals had only four so-called immediate compliance rules to meet in order to qualify for full licenses, yet only 56 percent were able to qualify. By 1959, with the immediate compliance list including 124 of the 180 rules, 90 percent of Michigan's hospitals qualified for full licenses.

The Michigan experience, Corneliusson and Keayon said, has taught the State health department that:

Leaders among hospital administrators, practicing physicians, and nurses are eager to work with a governmental agency in development of standards which will be administered by the agency. Having shared in setting standards, they become the best interpreters of them.

It is more satisfying to the hospital and the health department when a hospital improves its practices or facilities as a result of good consultation or education rather than because of big stick action.

Community Mental Health Management Reviewed

To generate understanding of mental health in a community, professional personnel may well have a long, hard road to follow, Dr.

Arthur J. Bindman and Dr. Lewis B. Klebanoff of the Massachusetts Department of Mental Health said, reporting on administrative problems inherent in establishing a community mental health program.

Although mental health is considered a virtuous and worthy cause, many varied attitudes are encountered. These attitudes must be understood and evaluated before professional personnel can work effectively for mental health in any locale, the authors stated. Goals cited for community leaders were the ability to see beyond individual interest in demands for service and to accept the limitations set by staff and budgetary boundaries.

Massachusetts was a pioneer, according to the authors, in establishing a mental health program based on local-State sponsorship of permanent mental health centers. This approach replaced traveling child guidance and school clinics, operating part-time on the local scene.

Community understanding, they said, may be encouraged by planned efforts in general mental health education, knowledge of the variety of services offered by a community mental health center, and promotion of support, both moral and financial. The authors urged emphasis on the partnership aspects of local and State participation and the use of the indirect approach in community organization.

A community mental health center, the authors suggested, can benefit from a clear pattern of communication and coordination between local and State departments; community acceptance through representation on advisory groups of organizations concerned with mental health; adequate financing; inservice training, standards, and salaries; and active relationships with schools and other caretaking agencies.

New Jersey

The role of the local health department in mental health, as explored in a 2-day workshop conducted by State and local agencies in New Jersey, was reported by two

participants, Dr. Jesse B. Aronson, director of the division of local health services, State Department of Health, and Dr. V. Terrell Davis, director of the division of mental health and hospitals, State Department of Institutions and Agencies.

The workshop, requested by a group of New Jersey health officers, opened the door to active local health department participation in programs of prevention and control. The authors said all participants stressed the need for wider use of available services, either in modified or expanded form, in any attack on mental illness in the community.

In general, there has been a tendency to consider mental illness as separate and apart from other diseases, the authors observed, with the following results: Local health departments have not considered mental health a primary public responsibility. Popular understanding of mental illness is delayed. Existing community facilities are not used as effectively as desirable, and in fact are duplicated in some instances at additional cost to the taxpayer. And treatment services are emphasized rather than preventive measures.

The health officer, because of his accepted position in the community structure, can perform the urgently needed function of coordinating independent community mental health services with existing community services for the prevention and control of other diseases, the authors concluded.

Radiation Safety: The Inside Story

The significance of the ingestion of radioactive materials in the light of man's total exposure to ionizing radiation was discussed by James G. Terrill, Jr., assistant chief, Division of Radiological Health, Public Health Service.

Human exposure to the external and internal hazards of ionizing radiation results in somatic and genetic damage which may or may not be immediately apparent.

In order to judge the significance of radiation hazards and the control measures that are necessary, Terrill stressed the importance of the overall identification of sources and evaluation of exposures.

The cumulative effects of ionizing radiation are influenced by the half-life of the source and the nature of its emissions. Terrill indicated that other factors are involved including the total effects of a combination of internal emitters; the tendency of certain emitters to concentrate in specific tissues, organs, or locations; variability of effects with age; the question of linear versus threshold dose-effect relationships; and the uncertainty as to the distribution and movement of radionuclides through the environment, and through the human body.

With the increasing concern over the exposure of the general population to ingested radioactive material, Terrill noted that the need for radiation health standards applicable to this group is becoming more acute. The terminology of "maximum permissible concentrations," while applicable to occupational exposure, presents many difficulties in interpretation of the health significance of the levels of a mixture of fallout and reactor effluent which will be measured by the public health agencies.

Terrill stated that the question of standards for the general population was considered during the 1959 fallout hearings held before the Joint Committee on Atomic Energy—the conclusion being that "standards do not (and cannot) set a line which is 'safe' on one side and 'dangerous' on the other." In all exposures to ionizing radiation, he emphasized, there is a calculated risk.

Another difficulty he mentioned is the issue of deciding whether the standards should apply to population averages, to peak values for individuals as they do in occupational exposures, to individual materials, or to average diets.

Such issues, he concluded, explain the need for developing data on effects of radiation, methods of meas-

urement, and total exposure as a guide to practical methods of control which may contain the risk with assurance and yet permit useful and beneficial applications of nuclear science.

Women Employees Affect Absenteeism Rates

Industry absentee rates and the shifting occupational distribution of women were discussed by Evelyn S. Spiro, labor economist with the Woman's Bureau, U.S. Department of Labor, in a review of the health and safety of working women.

The number of women workers in the Nation, more than 22½ million, may grow to some 32 million by 1975, predicted Spiro. Now they represent a third of the total work force, two-thirds of the clerical and more than half of the service workers, and almost all of the domestics. Although the professional and technical group has been growing at the most rapid rate, its proportion of women has declined. She believes that in the 1960's durable goods manufacturing will employ substantially more workers and the textile, tobacco, and leather industries, fewer. Among the women workers themselves, about a third are clerks.

Absenteeism data, though still fragmentary, in the opinion of Spiro, shows that time lost for job injuries is generally less for women than for men, but that women's frequency of nonoccupational disabilities is higher. The most days are lost for disability by the lowest income group. In a nationwide study of sickness absences of 5 consecutive weeks in cooperating establishments, frequency and duration rates increased by age for both sexes. The frequency rate for women was four-fifths higher than for men, with differences greatest in the 25- to 35-year age bracket. Among women, frequency was generally higher in manufacturing, in nondurables output, and among production workers rather than salaried. The average duration of these prolonged ab-

sences was 10½ weeks for women, about 2 days less than for men.

Spiro referred to a company study in which most sickness absenteeism was found to be among a few employees who were more discontented and prone to nervous and emotional disorders than others. Women averaged twice as many absences as men but of half the duration.

Fewer accidents occur in occupations and industries employing many women, said Spiro, except for some, such as poultry packing and certain other types of food processing, and in laundries and retail food stores. The average injury severity rate in 1956 and 1957 for apparel workers, mostly women, is the lowest in manufacturing.

In work such as canning and preserving, Spiro thinks that a high frequency of injury may be due partly to seasonal, short-term operations employing casual or inexperienced workers for long hours and deferring of repairs to the end of the rush season.

Attendants and food service workers were among those having the poorest safety records among hospital employees, who seem occupationally disposed to trunk injuries. Tuberculosis, viral infections, and skin disorders were the most common occupational diseases among hospital workers.

Men Report Less Illness Die Earlier than Women

That men run greater risk of life-endangering illness than women is suggested in a study reported by Dr. Lawrence E. Hinkle, Jr., associate professor of clinical medicine, Cornell University Medical College, New York City. Women may appear to have more illness, he said, because they report more minor illness than men do.

The study, in which Ruth Redmont, Norman Plummer, and Harold G. Wolff collaborated, was a project of the New York Hospital-Cornell Medical Center, covering disabling illness among 116 men and

96 women, New York Telephone Company employees, comparable in environment and other pertinent aspects, retrospectively for 20 years, and progressively for 5.

For both groups, the most frequent episodes concerned the respiratory and gastrointestinal tracts, musculoskeletal system, skin, eyes, and teeth. Men had a higher rate than women of such illnesses as pneumococcal pneumonia, pulmonary tuberculosis, and heart disease, bringing their death

risk rate to a ratio of 4 to 3 for women.

More frequent illness episodes for women than for men may stem from culturally determined differences in attitude toward acceptable disability for the man and the woman, said Hinkle, conjecturing that, rather than being "unhealthy," women were more easily incapacitated but harder. Further studies should "resolve the apparent paradox that mortality is inversely proportional to morbidity," he concluded.

serve University School of Medicine, Cleveland, Ohio.

He listed the following criteria to be met before any virus is incorporated into such a polyvalent vaccine used to immunize widely:

1. A clear demonstration that the virus causes the disease in question.
2. The disease is followed by immunity.
3. The virus can be grown in sufficient quantity to prepare a vaccine that effectively stimulates antibody.
4. A positive correlation exists between the presence of antibodies and resistance to infection.
5. Incidence of illness caused by the virus is great enough to warrant immunization on a broad scale.

Only the adenoviruses producing acute respiratory disease in military populations meet these criteria at present, he stated.

The acute minor respiratory infections with unknown causes constitute the bulk numerically of respiratory illnesses, Dingle said.

Of the 70 new viruses discovered in man in the past decade, nearly half were in the respiratory tract. Some have been identified as the cause of respiratory illnesses, some are associated with respiratory illnesses and also are present in apparently healthy persons, some appear to persist as latent agents in sites such as the tonsils and adenoids and play a minor role as provoking agents of disease, and others, seemingly unrelated to illnesses, have been termed "viruses in search of a disease."

At present, 18 types of adenoviruses have been isolated and more probably exist. The syndrome of acute respiratory disease in military recruits is caused principally by types 4, 7, and 14, and, to a lesser extent, by type 3. Aside from the outbreaks in summer camps and children's institutions characterized by pharyngitis, demonstrated to be caused by type 3, the importance of adenoviruses in causing disease in the civilian population is still uncertain, according to Dingle.

He described three new viruses, the parainfluenza viruses, in the

The Viral Diseases . . .

Live Polio Vaccine Spreads Lightly

An experiment to test the communication of live poliomyelitis vaccine, undertaken in two Louisiana communities in June 1959, was the subject of a preliminary report by Dr. Henry Gelfand, virologist, Public Health Service; Louis Potash, virologist, Merck, Sharp and Dohme; and Dr. John P. Fox, professor of epidemiology, Dorothy R. LeBlanc, and Dorothy I. Clemmer, instructors in epidemiology, Tulane University Medical School.

A surprising finding was that, under apparently ideal conditions, the virus spread from vaccinated children to unvaccinated children only to a limited degree. Instead of "an explosion of transmission," the virus was isolated from only 58 percent of contact families, from 39 percent of susceptible contact children, and from 19 percent of immune contact children.

Moreover, many of the contacts excreted virus for so brief a period that they could hardly have served as effective sources for its spread, Gelfand said. He added that such infections may have failed to stimulate either antibody or local intestinal resistance.

At the same time, 90 percent of the children fed live vaccine orally excreted homologous virus, indicat-

ing the achievement of some immunity. Vaccine strains of all three types were provided by Dr. Albert Sabin from pools that had fulfilled his criteria for purity and attenuation. Because of the specific status of immunity in the communities studied, only type 3 was used.

No illness was observed to result from any of the infections.

In his discussion of the results, Gelfand observed that if these findings are confirmed by future experience, "concern with possible enhancement of the pathogenicity of the vaccine virus during human passage may be minimized." At the same time, he saw little hope of conferring immunity to an entire population by the seeding of only a part.

The failure of the vaccine strain to infect a larger proportion of the contact children he attributed in part to relatively low infectiousness of the vaccine strain, as compared with "wild" viruses, and in lesser degree to viral interference.

Polyvalent Vaccine Standards Stiff

A vaccine containing all known agents associated with acute minor respiratory diseases is neither practical nor scientific at present, declared Dr. John H. Dingle, professor of preventive medicine, Western Re-

myxovirus group. Parainfluenza 1 virus was isolated in Sendai, Japan, from newborn infants suffering from viral pneumonia; parainfluenza 2, from patients diagnosed as having croup.

Almost all adults have antibodies to parainfluenza 3, formerly known as hemadsorption virus type 1, but whether this virus produces clinical or subclinical infection has not been determined with certainty.

Among other viruses isolated are the chimpanzee coryza agent (CCA), found in certain cases of pneumonia in infants and children, and the closely related 2060 and JH viruses, which are associated with mild respiratory illnesses.

Dingle concluded that knowledge of the causes of acute minor respiratory diseases is expanding and some semblance of order is emerging, although all the agents isolated account for only a relatively small proportion of the acute minor respiratory infections. He was confident that an important breakthrough has been made, and that the cause of the common cold, which occurs most frequently of all respiratory infections, will be found.

Mild Ills Offer Virus Clues

A mild febrile illness among families at the Great Lakes Naval Training Center in the summer of 1958 was investigated by Dr. Alfred D. Heggie, Dr. Irwin Schultz, Dr. Richard Gutekunst, Max Rosenbaum, and Dr. Lloyd F. Miller, attached to Naval Medical Research Unit No. 4.

Roughly a third of the families were affected by illness characterized by an upper respiratory infection and with associated gastrointestinal disturbances, enduring about 5 days, on the average. Fever and sore throat were the most frequent complaints. About a third of the patients reported headache and diarrhea. In a fifth of the patients, chest pains of a pleuritic nature were experienced.

The team found a "highly significant

association of the occurrence of illness with the isolation of virus from throat and rectal swabs" and attributed the outbreak to infection with Cocksackie B2 virus.

Viral isolation was about the same in all children under 12 years of age in the community, but there was significantly less illness in those of the group above age 6. Both illness and isolation rates were relatively low among adults. The team suggested that previous experience with the virus in the older children and adults may have modified response to the virus.

Although none of the more serious illnesses associated with Cocksackie viruses were found, the team suggested that studies of outbreaks of nonspecific febrile illnesses may aid understanding of the communication of Cocksackie infections and their control.

Bird Fever Distribution Thwarts Epidemiology

The virus which produces psittacosis is so widely distributed and so infrequently destructive to a human host that it presents special difficulties for the epidemiologist, some of which were described by Dr. Rex E. Graber, district health officer in Wisconsin.

Following a 4-year study of employees in a turkey processing plant, he found that "a practical means of preventing infected birds from reaching the processing line is not apparent." Infections in birds, as well as in humans, are usually subclinical, he added, and there is no practical diagnostic method for screening carriers. "Serological study and virus isolation, at their best, are slow, tedious, expensive, not easily available, and not sufficiently sensitive," he said.

At the same time, he recalled that Texas studies failed to yield evidence that there was a health hazard from cooking or consuming turkeys which came from farms known to have harbored infective strains of high virulence and toxicity. That assurance was issued in 1954. Con-

sequently, he felt that there was little hazard to consumers of turkeys from territories such as Wisconsin and Minnesota where the virulence of the strain is mild.

"Until control of the disease in the birds due to all strains is achieved," he said, "the first line of defense against the human hazard, in present day practice, must depend upon prompt recognition and treatment after the disease has been transmitted."

Usually, in Wisconsin, he said, physicians administer antibiotics early to patients acutely ill with symptoms and signs of respiratory infections. Such medication is effective against only a few of the primary causes of such symptoms, he added, but the physician also hopes by such treatment to prevent secondary infection. Tetracycline preparations have been found to be effective against the virus, but they also have the effect of preventing the production of detectable antibodies, with the consequent sacrifice of the opportunity of diagnosing the infectious agent.

Undoubtedly, he said, many sporadic cases of psittacosis from whatever source escape identification, and the number that might be associated with poultry is highly conjectural. Nevertheless, he believes there will remain ample opportunities for investigating this disease wherever birds are raised and processed in large numbers, unless by unforeseen methods the disease becomes controlled.

Need Way to Screen Rabies Immunity

Demonstrations of effective immunization against rabies still leave unanswered the question of identifying those who do not respond, according to Dr. R. L. Hectorn, veterinarian, Kentucky Health Department, and Dr. F. B. Peck, Jr., research associate, Eli Lilly and Company.

Using duck embryo for primary immunization, they determined that neutralizing antibody developed in a

majority of the subjects tested. Following the original 14-dose course, they found that only one or two booster shots seem necessary, once basic immunization has been established.

However, because of the few who fail to respond to immunization techniques, the authors refrain from offering a blanket recommendation for primary prophylaxis for rabies. Research is needed, they said, on a screening method to determine when immunization has been achieved.

Serum Sickness a Factor

When a patient develops serum sickness which is treated by corticosteroids in the course of administration of antirabies serum and vaccine, immunization may be defeated, in the opinion of Dr. Dorothy T. Magallon, on leave from the Kentucky State Health Department.

She had observed the usual incidence of serum sickness, about 20 percent, in 41 patients treated following bites by suspected rabid animals. In a group of 32 patients

given antihistamines with the serum and vaccine, one developed serum sickness. Blood studies on these patients suggested that antihistamines might be used to offset serum sickness without interfering with antibody levels. However, antibody studies on the patient who developed serum sickness and received corticosteroids showed a total lack of response to vaccine. This suggests that patients who develop serum sickness may be exposed unwillingly to the hazards of both serum and vaccine without acquiring protection against rabies, although further research is needed to confirm this premise and to define more clearly the place for antiserum in rabies prophylaxis.

The best insurance against rabies or complications of antirabies therapy, however, she said, is the discerning physician who will weigh the risk of treatment against the probability of infection, considering circumstances of exposure, extent and location of the wound, behavior of the animal, and prevalence of rabies in the community.

kets are brought into the operating room, that no street clothes or ordinary hospital uniforms be worn under gowns, and that no one enter or leave the room during an operation.

In the Middlesbrough public health laboratory, ventilation methods are being tested in a full-sized dummy operating room. Inflow of contaminated air has been prevented through the use of ports with weighted flap valves. When a door is opened and pressure in the room drops, these valves close and make the entire air supply available to give a strong outward draft through the door.

Blowers found that organisms inside the uniformly contaminated dummy room, where contamination arises below the table, are removed more rapidly by the downward displacement or "piston" method of ventilation than by other methods. This is effected by introducing clean air at the top of the room so that there is a minimum of mixing with the contaminated air which is removed by downward displacement. Also, fewer organisms are deposited on an exposed culture plate which represents the wound.

For an operating room, the best method of ventilation depends on exactly where organisms are discharged into the air. It is known, Blowers said, that few *S. aureus* are shed from the respiratory tract of nose and throat carriers and that many are shed from the skin and clothing of general skin and perineal carriers. What remains to be discovered, he suggested, is whether surgeons and nurses shed their *S. aureus* above or below the waist during their activities in the operating room.

Air Samples Measure Staph Contamination

The need for quantitative as well as qualitative analysis in studying the relation of the environment to hospital-acquired staphylococcal disease was stressed by Lawrence B.

Staphylococcus Control . . .

Operating Room Bacteria Controlled by Ventilation

Airborne infection of wounds during surgical operation is an appreciable hazard, declared Dr. Robert Blowers, director of the public health laboratory, General Hospital, Middlesbrough, England.

Reporting the results of air sampling during operations and sepsis records associated with them, Blowers said that when general bacterial counts were between 20 to 40 contaminated particles per cubic foot, the *Staphylococcus aureus* sedimentation rate was about 0.5 particles per square foot per minute. In operating rooms where efforts had been

made to reduce airborne contamination, general bacterial counts were as low as between 1 and 2 particles per cubic foot, with the *S. aureus* sedimentation rate roughly 0.005 per square foot per minute, thereby reducing considerably the occurrence of sepsis.

However, Blowers pointed out, because it is still unknown whether the sepsis that does occur is airborne, more observations must be made before bacteriological standards of safety can be defined.

Bacteria in the air can be reduced effectively only when a good ventilation plant is combined with operating room discipline, he said.

Blowers suggested that the surgeon insist that no unsterilized blan-

Hall, chief of the Equipment Development Section, Communicable Disease Center, and Herbert M. Decker, chief of the Protection Branch, Ft. Detrick.

Many improvements have been made in sampling techniques, particularly in air sampling. The techniques should be used wherever possible, they said, in order to learn the extent of contamination.

Hospitals are usually concerned with the contamination of fomites. Although it is possible to estimate the quantity of contamination of a fomite, as well as its character, Hall and Decker cautioned that the quantitation is only relative, and the limitations of the procedures must be kept in mind.

The contamination of fomites is roughly similar to that of air and the degree of activity in the vicinity since the organisms on the fomites are readily resuspended in the air. To measure this route of transmission as well as droplet nuclei and similar particles moving directly from the host into the atmosphere, the contamination of the air can be sampled by a number of devices, some with only qualitative, some with quantitative characteristics.

Impaction-type samplers, although limited to the collection of bacteria, the authors said, are best suited to the demands of hospital use. For both bacteria and viruses, a liquid impinger can be used.

Hall and Decker described the various types of impaction-type samplers available, their operating characteristics, and their limitations.

They pointed out that the liquid impingers, the sieve, and the Andersen samplers provide both qualitative and quantitative information concerning airborne organisms. The slit-type sampler, because of its mechanical simplicity, its lack of manipulation of the sample after collection, and its time-concentration relationship, is particularly suitable for hospital use when the air being examined is essentially static. Particular advantage, they said, should be taken of the time-concentration

relationship since this information can be of invaluable assistance in pinpointing a route of transmission and contributing to the epidemiology of the disease under study.

Nursing Research Takes Bearings

For the nursing profession to participate in scientific investigation of the effectiveness of its practice, declared Margaret Thomas, nursing consultant, Epidemiological Branch, Communicable Disease Center, it must clearly delineate this practice and join with the medical profession and related fields in setting up suitable methods of study.

Because nurses' inquiries about aseptic techniques made apparent the need for more specific recommended procedures in the control of staphylococcal infections, a status survey was made of the practices used in the obstetric departments of 13 medical centers.

The objectives of the survey were to determine what aseptic procedures were being used and whether they were used consistently, whether there was a relationship between the diligence with which the nurse carried them out and the incidence of known infections in the hospital, whether any studies had been done in the institutions for determining procedures to be used or their effectiveness, and how well currently recommended standards were being met.

Although a critical analysis of the results of the survey has not been completed, Thomas cited some of the general impressions of the investigators.

- Nurses seemed eager for consultation and for someone to listen to their ideas. They were zealously striving to enforce what they believed to be protective procedures.

- All infections committees of the institutions had nursing representatives who were not only involved in establishing control measures, but in some instances were actively engaged in maintaining reporting systems.

- Hospital administrators ap-

peared anxious to protect their patients. The recognition of the importance of space and equipment in prevention and control of infections was evidenced by new construction and remodeling.

- On the negative side, the investigators found that the surveillance programs were not sufficiently organized to permit study of the relationship between incidence of infection and the adequacy of aseptic practices.

- The lack of knowledge of scientific principles was obvious. There were few instances of original scientific study as a basis for establishing aseptic practices. Most of the existing studies were in housekeeping departments and were mainly concerned with blankets and detergent sanitizers.

- There was an apparent lack of concern about time-temperature relationship in heat sterilization and time-dilution relationship in chemical sterilization.

- Many inconsistencies existed among the hospitals and even among the services of a given hospital. Examples of inconsistency were found in the length of time required to re-autoclave sterile equipment, different hand-scrub techniques for surgery and delivery rooms, and variance in the use of caps, gowns, and masks between surgery and obstetrics, also among types of personnel.

Nurses have assumed responsibility for investigating standard nursing procedures. However, Thomas said, they feel that this responsibility is not incumbent on them for procedures prescribed by the physician. The nurse has a professional responsibility for her personal hygiene. She should know how to protect her clothing from her patients and her patients from her clothing. She should determine a safe method for keeping her hands clean and whether the use of a mask would be a safety device for her or the patient. Unquestionably, the nurse develops the procedure for bathing adult patients, yet for the

care of an infant's skin she waits for medical prescription, she continued.

Therein, Thomas pointed out, lies the problem of not having specific answers to seemingly small details. The medical profession has not investigated prescribed nursing procedures extensively because its time

and interest are logically focused on the more scientific clinical factors of patient care.

Thomas believes that a committee representing various disciplines concerned with hospital patient care and management will provide a "common sense" approach toward such issues.

The Chronic Diseases . . .

Industry Know-How For Public Health

For combating chronic diseases, Dr. A. L. Chapman, Assistant Surgeon General of the Public Health Service, urged public health workers to employ methods that have proved their value in the commercial world, such as motivational research, product development and marketing, mass production, and automation.

Chronic diseases, he said, are an economic drag, contributing as they do to the dwindling number of producers in relation to the number of consumers in the United States. According to the National Health Survey, approximately 17 million persons are limited in their activities by a chronic condition and 1.1 million are confined to hospitals.

Long-lasting diseases, resistant to therapy or cure, absorb expensive quantities of goods and services for treatment, he stated, with no economic return.

Awareness of the economic drain of chronic diseases is apparent in the growth of dollar appropriations to the National Institutes of Health and other research organizations, Chapman said, although support for the application of research findings has been uninspired. Spending millions for research and pennies for application is like buying bread and not eating it, he commented.

Chapman advocated that the accounting practice of balancing product development with marketing, sales, and distribution be adopted in public health. He asked, Why do

children with rheumatic fever fail to get penicillin prophylaxis? Why are half the people in the United States with diabetes unaware of it? Where is the weak link in health's production line?

A conviction that ineptness in changing attitudes is one of the big handicaps of public health workers is responsible for the current rash of motivational research in the field.

He recommended also that automation and mass production will help laboratories to handle the growing analytical load of periodic physical and screening examinations. How else can the average laboratory handle a 10-fold increase in the present number of tests being performed, he asked. There are signs—the clinitron, the cytoanalyser, and the autoanalyser—that changes along these lines are in the making.

The laboratory director of the future, he predicted, will have to be teacher, trainer, researcher, and administrator as well as analyst. He will also have to obtain and commit a great deal more money to research projects and promote greater interest in the bread-and-butter importance of what his laboratory is doing.

Glaucoma Day Furthers Community Services

The outcome of two Glaucoma Days in Santa Barbara, Calif., has been high casefinding rates and an awareness among ophthalmologists

of community needs for preventive services, reported Dr. Helen Hart, health officer of Santa Barbara.

On G-Day in 1956, 680 persons were screened, 192 referred for followup, and 47 found to have glaucoma. On G-Day in 1958, 680 were screened, 97 referred for followup, and 11 found to have glaucoma. The median age of the 1956 group was 66.2 years, of the 1958 group, 61.3 years.

Participating in the preparation, screening, and followup of the 1956 event were the California committee of the National Society for the Prevention of Blindness, Santa Barbara's ophthalmologists and their office staffs, Delta Gamma Sorority, Santa Barbara Eye Foundation, Blue Cross, school and county health department nurses, the city health department, an optical company, the county clinic, and a drug company.

The screening at the city recreation center included visual acuity, fundus and tension examinations, and an interview.

Hart described the followup activities. Persons with definite or suspected glaucoma who did not have their own ophthalmologists were assigned to one according to an alphabetical list. They included patients who were unable to pay or who stated they could pay a reasonable fee. Appointments were arranged at the county clinic for those eligible to receive care there. Ophthalmologists were asked to notify the health department of any patients in the definite or suspect categories who were not seen. Persons with other eye conditions were notified and advised to seek medical care.

The community's ophthalmologists initiated and planned the second Glaucoma Day in 1958, delegating specific tasks to the same groups who cooperated in 1956. Screening and followup activities were similar to those carried out in 1956.

Hart counted these additional benefits of Glaucoma Day. The ophthalmologists regard recurring G-Days as a way to serve the community and inform the public about eye conditions. Also, they have be-

gun another community service: vision testing of preschool children. The health department, in providing counseling, statistical, and followup services, gained understanding of its functions among the ophthalmologists and furthered a chronic disease program.

Cancer Tests Given Scotch Verdict

Experimental carcinogenesis in animals was reviewed by Dr. R. E. Eckardt, director, medical research division, Esso Research and Engineering Company, Linden, N.J., with emphasis on the public health interest in the inconsistencies, limitations, and drawbacks of available techniques for evaluating food additives. Final judgment in many instances, he indicated, must be the Scotch verdict, "not proven."

Eckardt stressed that the species of animal and type of test should be considered in evaluating carcinogenic properties of chemicals for public health purposes. He cautioned against oversimplification by commenting on the inadequacy of fluorescent spectroscopy for determining carcinogenicity. Many non-carcinogens fluoresce. And fluorescence can be quenched in others. In the biological field, he illustrated inconsistencies of responses to the same material by describing identical research with various animals, comparing the effects on the species.

Eckardt recounted experiments on subcutaneous tissues which indicated that the physical state of a plastic material might determine its carcinogenicity. Observing that subcutaneous injections of sugar and cholesterol produce sarcomas in rats and mice, he concluded that subcutaneous tissues are inappropriate test sites for evaluating the safety of food additives.

Polyaromatic hydrocarbons produce tumors on the skin and cancer in the forestomach of mice, Eckardt said, but the forestomach of the mouse is lined with squamous epithelium, not glandular epithelium as

in the human. He noted that aminoazo compounds fed to rats result in liver tumors; however, there appears to be no counterpart to these experiments in man. Protein and riboflavin in the diet, he remarked, afford protection against these tumors; so does 0.003 percent methyl cholan-threne, a potent skin carcinogen.

Differences in susceptibility to specific carcinogens was confirmed by the observation that exposure to B-naphthylamine, and probably benzidine, produces bladder tumors in dogs and man, but in mice only when pellets are surgically implanted into the bladder. Eckardt suggested that it would be advantageous to develop understanding of the metabolic pathways involved with chemicals that induce tumors and cancers in various species of animals because if similar metabolic pathways are not present in the human, the likelihood of this compound being carcinogenic to man is probably quite remote. Recalling that 2-acetylaminofluorene, developed as an insecticide, produced a profusion of tumors at multiple sites in a variety of animals, he reaffirmed the need for testing.

In the field of food additives, Eckardt declared, experimental carcinogenesis is in its infancy. More basic fundamental research is needed. There is no one test or battery of tests of carcinogenicity which are appropriate for determining the safety of food additives. He recommended evaluating each compound to determine its chemical nature, probable concentration in the food supply, carcinogenicity, metabolic pathways in man and animals, and importance in our food technology.

Planned Prophylaxis Cuts Rheumatic Fever Toll

Cooperative planning for rheumatic fever prophylaxis in Connecticut since 1955 was described by Dr. Nicholas P. R. Spinelli, chairman of the Rheumatic Fever Committee, Connecticut Heart Association, Horace A. Brown, executive director, and Nicholas J. Lavniko-

vich, program director, of the association.

An investigation and planning committee formed by the association advised intensive, statewide professional education on prophylaxis, as a foundation for the program. Through cooperation of the State's pharmaceutical associations, negotiation, and competitive bidding, "prohibitive" penicillin prices were lowered. Indigent patients received penicillin free. Physicians applied to the association for medication for each patient. The application form states the criteria used by the physician for diagnosis of acute rheumatic fever. Four prescriptions with coded stubs, a year's penicillin doses, were issued to each approved application. Weekly coded stubs were returned by wholesalers to the association for records on patients' prophylaxis maintenance. When the fourth prescription stub was returned, a reapplication form was sent automatically with queries on the patients' progress, cooperation, and other infection and recurrence information.

Each recurrence is investigated by the committee's area physician. Bona fide recurrences have been low. Patient delinquency has also been cut significantly by dropping those not using prescriptions for more than a year.

They attributed a 20-fold rise in the number of streptococcal cultures projected for 1959 over 1954 to education efforts.

They suggested that pregnancy may be a strong factor in casefinding because in the childbearing ages, 25-44, about 65 percent of the patients were women, as against a 57 percent proportion of women among all patients. The 25-44 age group accounted for 33 percent of all in the plan. Throughout, the usual relations of patient to physician and pharmacist were maintained.

New York Experience

Another example of cooperative planning and operation in a rheumatic fever prophylaxis program

was reported by Dr. Katharine D. Brownell, director of the Manhattan Cardiac Program, New York City Department of Health, Margaret A. Losty, acting director of the department's bureau for handicapped children, and Helen M. O'Shaughnessy, director of community program, New York Heart Association.

The New York City Health Department and the New York Heart Association worked together within an established pattern of cooperation to set up a prophylaxis plan. Coordinated by a joint committee with visiting nurse representation, the program reaches more than 4,000 patients. Major obstacles were the high cost of penicillin and insufficient clinic staff for followup, revealed in a 1953 survey. These were overcome in large part by the association's purchase of oral penicillin for patients at clinics with approved programs and grants of heart association funds for selected followup services. The city also supplemented the supply of oral penicillin for clinics and the welfare department made it available for its clients.

In addition to intensifying case-finding in schools, for referral and followup, the health department promoted prophylaxis among physicians through consultations. The joint committee arranged discussion groups and guides for physicians.

The authors observed that in the two special health department prophylaxis clinics in the plan, verification of diagnosis has been acceptable to the referring physicians. Pinpointing followup as a weak element in the program, they consider that it can be strengthened by adequate clerical staff and well-planned and well-maintained files, supplemented by followup by the clinic social worker and the school nurse.

Followup is hampered also, they said, by frequent changes of residence and by the difficulty of keeping in touch with newly adolescent patients. A central registry

is helpful in maintaining followup of these groups.

The voluntary agency has been serving primarily as a catalyst, they concluded. It has also backed, on a demonstration basis, a clinic program reaching a large proportion of the city's medically indigent patients. In the development of a wider program under health department responsibility the support of other agencies, both official and voluntary, and practicing physicians, must be obtained.

The Michigan Program

Physicians receive free prophylactic agents for treating rheumatic fever patients in nonacute stages in Michigan's statewide prophylactic program. In administrative structure, Dr. Carleton Deau, director of the Michigan Crippled Children

Commission, and Dr. George H. Agate, epidemiologist, City Health Department of Lansing, said the program utilized the pivotal role of the family physician.

Beginning January 1956, on termination of a successful pilot project in the Upper Peninsula, the Michigan Crippled Children Commission and the Michigan State Department of Health joined efforts. The health department distributes penicillin G and sulfadiazine to physicians and the commission finances medical supervision of injections to children in the commission's regular program.

Dean stated that continuous year-round medication was recommended for an indeterminate period. Rather than daily oral medication, monthly intramuscular doses of benzathine

Bargain Exhibits

Two outstanding exhibits at the APHA conference, cited for excellence, also were models of economy.

The Public Health Service exhibit on seat belts, probably the busiest in the hall, was built for less than \$150 and can be duplicated for much less. It consisted of a table bearing a model of an urban street intersection, and four toy automobiles, built to explode on impact. These toy cars were purchased in a drug store. The only modifications for the exhibit were that toy figures were seated in the cars and rubber bands were installed to simulate seat belts for some of the "passengers." When the cars collided, passengers not restrained by the "belts" were thrown into the street, with impressively disastrous effects.

The Brookline (Mass.) Health Department exhibit on glaucoma, constructed at a cost of only \$50, was used in connection with the glaucoma clinic sponsored by the Brookline Lions Club and the Brookline Health Department. The message of the exhibit was: "Glaucoma should be found! Two to four percent of adults over 40 have glaucoma! Brookline finds it!" At no additional outlay, the exhibit was built around a slide projector owned by the health department. Twelve colored slides enabled a viewer to accompany a patient through the various steps and procedures of this clinic.

pencillin G were found to facilitate supervision of patients. Dean suggested that the child patient's emotional reaction to monthly injections might be studied as related to the plan's success.

When a child discontinues treatment, the commission queries the physician first. If no explanation is found, it writes the family. Follow-up continues if the family has moved. In the period, January 1, through June 30, 1959, 393 children were receiving prophylactic treat-

ment under the commission's jurisdiction. Excluded were 10 cases dropped because they could not be located after residence change and 10 others who discontinued treatment for unknown reasons.

Among needed ingredients for a good program, Dean mentioned cooperation of parents and the availability of diagnostic and consultation facilities, as well as the understanding and cooperation of the practicing physician in the community.

Flesch reading ease formula, Hoyman said, adding that statistical formulas were used to test the significance of the mean differences at the 5 percent level of confidence.

The findings, which agree with the pilot studies of Taylor, Hanson, and Zaharko, indicate that:

- Some widely used modern high school health textbooks, especially those used in ninth grade classes, are probably too difficult for average, below average, and poor readers to use effectively.

- Other widely used health textbooks, especially those used in the tenth grade or higher, are too easy for above average and superior readers.

- Apparently most new editions of health textbooks retained previous reading difficulty levels.

- None of the textbooks studied appeared to use reading difficulty progression, from less difficult material at the beginning of the book to more difficult in later chapters.

- The use of one health textbook for all students in one high school grade is apt to mean that the text is too easy for some and too difficult for others.

Many complex factors contribute to reading difficulty, Hoyman said, mentioning content, style, organization, and format. Readability yardsticks, such as the Flesch formula, test factors related to style only as a determinant of reading difficulty. The Flesch formula should not be expected to supply answers about the other aspects of readability of high school textbooks on health, Hoyman emphasized, although such tests do give valuable information in any effort to supply the students with an appropriate text.

Recommendations by Hoyman included discontinuance of the widespread practice of using one health textbook for all students in a given class or grade. The use of several textbooks permits individual assignment according to reading difficulty. He also suggested the possibility of reorganization of high school students into homogeneous groups within a grade or class, ac-

Youth Habits . . .

Good Adolescent Driving Reduces Traffic Toll

"In our culture, a child is passed from one authority to another—home, school, church, community. He is observed, evaluated, and regulated. And then suddenly he can get in his car and drive far enough in a short time to be anonymous and free, free to maim and kill himself and others. What is the solution?"

Dr. James L. Malfetti, executive officer of the safety research and education project of Columbia University, presenting this theme, stated that authorities claim drivers cause between 80 and 90 percent of the traffic accidents in the United States. He emphasized that drivers 16 to 24 years of age cause a disproportionately large number of the accidents which kill approximately 40,000 people a year.

Stating that if we can do something about adolescent drivers, we can significantly reduce the total number of accidents, Malfetti called first on parents to set a good example. He also called upon community leaders to build recognition of moral responsibility for traffic damage, injuries, and death through talks with license applicants. Other recommendations by Malfetti were:

- Higher quality tests for licenses.
- Realistic speed regulations.

- Improved driver education courses, emphasizing student decisions on good driving techniques.

- Rewards for courteous driving and lifesaving maneuvers.

- Clinics for chronic adolescent traffic violators.

Malfetti recognized that no driver, adolescent or adult, is immune to accident-producing behavior. He urged full use of mechanical devices in accelerating, steering, and braking, to correct or warn drivers when safe limits are exceeded. Such devices are available, Malfetti said, and others can be developed.

Rather than attempts to change basic personality traits of drivers, Malfetti recommended full use of techniques to curb the automobile when the driver fails to function at his efficient best.

Teaching Health To Teenagers

Textbooks on health for high school students are too difficult in some instances and in others so easy as to be boring, according to Dr. Howard S. Hoyman, head of the department of health and safety education, University of Illinois, and his assistant, Aubrey C. McTaggart.

Eleven widely used high school textbooks on health were tested for reading difficulty using the 1948

cording to their reading and learning ability.

New Thinking Needed On Teenage Drinking

Educators of teenagers are behind the times in methods of teaching the inherent dangers of drinking, Raymond G. McCarthy, associate professor of health education at Yale University, suggested.

Teaching about alcohol has been required by law for many years in every State, he said, but primarily to encourage total abstinence by emphasizing the dangers of drinking. The ineffectiveness of the psychology-of-fear approach is apparent in the fact that approximately 70 percent of all adults over the age of 15 years use alcoholic beverages. Research among high school students in New York, Wisconsin, and Kansas, he continued, reveals a substantial proportion of drinkers, many with parental consent.

McCarthy believes these statistics challenge the traditional classroom approach to alcohol education in public schools. Information about the bizarre results of alcoholism, which affects roughly 6 percent of all users of alcohol, is of little significance to teenagers, he stated, adding that it would be more realistic to emphasize the dangers of intoxication and its attendant traffic accidents, violation of family or church standards, and behavior disturbing to the individual.

Teaching should embody a set of facts about alcohol as well as consideration of different attitudes toward alcohol use and nonuse in our society. The schools have not translated this change in cultural attitudes into classroom practice, McCarthy concluded.

Teens Determine Smoking Habit

Smoking in the United States can be curbed best by informing young people of its risk to health, asserted

Dr. Roger S. Mitchell, director of the Colorado Foundation for Research in Tuberculosis and associate professor of medicine, University of Colorado.

Stating that cigarette advertisers direct multimillion dollar campaigns to solicit "still unaddicted teenagers," Mitchell said, it would not be a bad idea to "take a leaf out of their book."

In reviewing what he termed "presently available facts with regard to smoking and health," Mitchell reviewed published data on the rising tobacco consumption for the past 60 years; total death rates by age and smoking habits; mortality ratios by amount of smoking, for ex-smokers, and for various causes of death; various causes of excess deaths among men who smoke regularly; male death rates for various diseases and lung mortality rates for men, by amount smoked; lung cancer mortality rates for rural and urban residents; comparative smoking habits of men and women; and trends in environmental factors.

Mitchell believes smoking is one of the multiple causes of lung cancer; shortens life by at least 5 years, through increased risk of atherosclerosis, cancer, and chronic obstructive airway disease; shortens breath; impairs physical performance; and aggravates or delays healing of stomach ulcers.

High school students can be taught the hazards of smoking, Mitchell stated. He recommended:

- Efforts to engender student requests for health education on smoking.
- Question and answer sessions.
- Participation by parents, local and national medical societies, health organizations, and legislators.
- An adult approach, emphasizing the maturity of self-restraint and discipline.
- Minimal smoking, preferably pipes, for those addicted.
- Research which will lead to the elimination of injurious factors in smoking.
- A good example by parents and adult associates.

Gerontological Studies . . .

Aging Population Needs New Mores

With a significant increase in average life expectancy, major social changes are needed to reap full advantage from the added years. In the opinion of Dr. Edward L. Bortz, medical service chief, Lankenau Hospital, Philadelphia. Customs and social attitudes, he says, ought to esteem maturity and recognize its potentials. Also, he said, the family must be bolstered as a setting for aging.

A new index for aging, based on biological condition, such as performance and capacity, Bortz said, would be a more satisfactory yardstick than the calendar. However, much of so-called physical evidence of age, he said, is actually evidence

of conditions which with foresight could be prevented or at least delayed.

Citing the ramifications of a Cornell longevity study on laboratory animals, Bortz envisions an average human life of 100 healthy years. These he divides into trimesters, the last called the "summit of the years," in which intellectual growth and social participation may continue after 80. Much deterioration is avoidable through sensible health practices, he pointed out, referring also to promising experiments to retard deterioration of tissues of the vascular, skeletal, and nervous systems.

Deploping the current practice of retiring healthy and active workers from established occupations, he stated that a second career could

begin at 65, with retirement deferred to 85 or 90.

Physicians and medical educators, Bortz concluded, have a major function in determining whether or not the added years are to be characterized by weakness, depression, and deterioration, or "by flowering of the major powers inherent in each citizen."

Aged Seek Services More Than Beds

To weigh the present and future load of chronic ills in Monroe County, N.Y., the agencies concerned and their patients were analyzed in a study reported by Walter Wenkert, secretary of the health division, Council of Social Agencies, Rochester, N.Y., and Dr. Milton Terris, professor of epidemiology, Tulane University School of Medicine. A major conclusion is that strengthened services may obviate the need for additional beds.

The 18-month study was originated by a citizens committee and financed by the Community Chest and the County Board of Supervisors. Eight general hospitals, 4 long-term hospitals, 30 private nursing homes, 8 infirmaries of homes for the aged, and 16 public health nursing agencies were questioned about admission and discharge policies, scope and purpose of services, staffing patterns, staff education and training, costs, income, and future plans.

The medical staffs or administrators of the agencies and institutions supplied 1-day census information on 3,780 patients. Each member of a clinical review team (physician, public health nurse, and social worker) independently interviewed 179 patients, a random sample of the census group.

The clinical review team differed with the staffs of the agencies in judgments of appropriate levels of care. The team felt that 85 percent of the hospital patients, but only a third of the home care patients, were receiving care at the appro-

priate level; the agency staffs felt that 41 percent of the hospital patients and 70 percent of the home care patients were at the proper level of care.

If the team's judgments on levels of care are projected to the total study population, new and strengthened services should be planned and created before installing additional hospital, infirmary, or nursing home beds, the authors concluded.

They pointed out five major gaps in services which the study disclosed.

- *Physicians need the assistance of nurses, psychologists, physical therapists, social workers, and other professional persons to evaluate a patient's total care requirements.*

- *Rehabilitation services, in the form of occupational therapy, medical social work, and recreation, as well as physical medicine, are needed in hospitals, nursing homes, homes for the aged, and for home care patients.*

- *Of the 3,780 patients, from 88 to 554, if the review team's judgments concerning the random sample are projected to the total study group, need organized home care.*

- *Agencies, because they are limited by their special concerns or by other requirements, are unable to provide the multiple services needed by patients with chronic disease.*

- *Although there were 76 clinical projects related to chronic disease in the county, no research was being done on the administrative, operational, or service aspects of long-range care. There were no formal affiliations among institutions providing different levels of care to share professional services and facilities.*

Plans to pursue specific recommendations of the study are being made by these institutions: A home for the aged is evaluating intake policies. A hospital is preparing a comprehensive rehabilitation program. A hospital, the health department, and the visiting nurse service are developing an organized home care program. Joint services are being arranged between a gen-

eral hospital and a home for the aged. A convalescent hospital for physically handicapped children is being closed. The council of homes for the aged is defining and cost accounting levels of care. Blue Cross, the medical society, the hospital council, and the study's followup committee are increasing voluntary health insurance coverage among the aged.

First Admission Study Asks Why Aged Crack

Causes of mental breakdown among the aged were sought in a study of the background of 26,645 first admissions to Ohio State mental hospitals January 1948 through June 1952, reported by Ben Z. Locke and Dr. Morton Kramer, biometricians, National Institute of Mental Health, and Dr. Benjamin Pasamanick, research director of the Psychiatric Institute and Hospital, Columbus, Ohio.

Of the total studied, 5,676 were diagnosed as having mental diseases of the senium. These, it was observed, were more likely than not to come from cities, to be male, to lack higher education, and to be divorced, separated, or single rather than married. Among women, the rate of admission was higher for those employed at jobs other than housework. Among men, occupations having the higher rates of admission were laborers, farmers, service workers, and craftsmen.

For confidence in these findings, the authors remarked, supplemental data is needed on mental illness among the noninstitutionalized and in other facilities for aged mental patients.

Although population records suggest the probability of a marked increase in admissions of mental patients with diseases of the senium, by 1980 more than 60 percent above the 1950 level, there are social changes which they feel may offset this trend.

Apart from population changes, there may be developments in institutional care, community services, and home visiting, they said, which

will affect the mental conditions of the aged. Attitudes of both the aged and the community also may be altered, they suggested, in a direction that will reduce present mental distress. For example, they mentioned services which would offset the mental and physical effects of inactivity and confinement, or attitudes which would help the ex-breadwinner to adjust to a new status.

On the whole, the authors believe changes are in the direction of supporting mental health for the aged. Physical labor, they predict, will become less taxing, income more certain and more nearly adequate, constructive use of leisure time more common, nutrition and other health services strengthened, and educational levels raised. The character of institutions for the aged, they predict, will become more acceptable also.

Mental Ills of Aged Need Special Care

Knowledge of the role of homes for the aged in meeting the health needs of our senior citizens is meager, reported Dr. Franz Goldmann, director of health study, Council of Jewish Federations and Welfare Funds of New York City.

A large-scale inquiry into coordination of medical care in chronic illness, supported by the Public Health Service, presented an opportunity to investigate the part played by homes for the aged. Cross-sectional case studies made in the spring of 1958 covered 530 residents of five Jewish homes for the aged, in Chicago, Miami, Philadelphia, St. Louis, and Toronto. Descriptive material on organization, functions, and relationships in 1957 was collected from 70 such homes in the United States and Canada.

Findings, according to Goldmann, showed almost all of the 530 residents of the five homes have multiple chronic ailments. Many are substantially disabled. The well resident is the exception.

The most common affliction is men-

tal impairment, with symptoms of temporary or continuous confusion. Marked emotional disorders are widespread among the residents studied, Goldmann reported.

The detailed analysis of 70 homes revealed that most of these institutions perform the functions of high-grade nursing homes and emphasize comprehensive health service, including psychiatric care, and teamwork. Goldmann said the

experience gained at homes with relatively advanced psychiatric service clearly demonstrates its value to the patients and the possibility, through more widespread use of such service, of reducing transfers to mental hospitals to a minimum.

A realistic policy is needed, Goldmann added, for both the long-term institutional care of persons in ill health and the housing of senior citizens capable of self-care.

Water and Wastes . . .

Contract Health Services Overcome Complexities

Small municipalities, financially unable to maintain a health officer and health services of their own, are contracting for such services through county or State health departments, according to H. Clifford Mitchell, director of sanitation, St. Louis (Mo.) County Health Department.

A number of such communities have purchased sanitation services, and school districts have obtained mental health, dental, and nursing services through contracts in the past few years, Mitchell reported. His own division of sanitation, which serves the metropolitan St. Louis area excluding the city of St. Louis, has in 5 years expanded its services in this way to more than 200,000 persons previously without health services, he said.

St. Louis County's population increased from 274,000 in 1940 to 700,000 in 1959, and the number of its municipalities rose from 40 to 98, with an accompanying demand for municipal sanitation services such as refuse and rodent control, water supply, sewage disposal, swimming pool inspections, air pollution control, and industrial hygiene.

Legislation restricted the county health department from providing health services directly on a county-

wide basis, requiring each municipality to provide its own, but county ordinances made contract service possible.

The first attempt at such cooperation, limited to restaurant inspection and rabies control, was so well received, according to Mitchell, that in 1954 the county entered into a unique contract with the city of Jennings, Mo., population 18,000. Under this arrangement, the county health commissioner took on the duties of health commissioner of Jennings without an additional remuneration, one well-trained and experienced sanitarian was assigned to the community full time, and the sanitation code of the county was accepted by the municipality. The city supplied office space and all utilities and reimbursed the county for the sanitarian's salary and transportation.

At the end of a 12-month trial, the mayor and council of Jennings petitioned for continuation of the service indefinitely. Scores of other small cities followed Jennings' example, and the county department is now giving contractual services to 52 municipalities, Mitchell reported.

He pointed out that this procedure provides a partial solution to a tough problem and that both community and department gain from it. The municipalities receive their necessary sanitation and other health services from competent personnel at reasonable cost; the county health depart-

ment gains through development of closer ties with cities and greater control over countywide problems of public health.

Mitchell admitted it would be easier and less cumbersome to have sufficient funds and appropriate legislation to provide uniform services throughout the county without regard to municipal boundary lines, but the contract program does keep department personnel on their toes to provide satisfactory service. They know they are directly responsible to the governmental agency which is contracting for the service and that contracts can be canceled upon 30 days' notice. The procedure has been studied by a number of organizations such as the League of Municipalities, the Ford Foundation, and the American Public Health Association, Mitchell said.

State Board Promotes Water Enough for All

Adequate water supplies, reported Dwight F. Metzler, chief engineer of the Kansas State Board of Health, are a basic public health responsibility. On this principle, State resources were directed to help communities in Kansas overcome recent, present, and prospective water shortages.

Deficient water supplies in American cities, he recalled, had been reported recently by the American Water Works Association, which found many American cities over 25,000 lacking capacity in water mains, pumping capacity, and storage facilities.

At the same time, demands for water have been complicated by increased per capita use in a growing population.

Although not a single case of waterborne disease is known to have resulted from deficiencies in their systems in recent years, many Kansas cities had come to the point of rationing water uses in the dry years of 1952-57. Following an investigation of the water shortages, the State discovered the main factor was not a

lack of water but a lack of planning for its storage, treatment, and distribution.

Emergency efforts to supply deficient communities included hauling, temporary treatment systems, cloud seeding, and reuse of waste water. Long-range efforts included evaluations of municipal supplies and encouragement of efforts to improve and expand water systems.

Metzler estimated that it takes from 3 to 5 years to proceed from the finding that facilities are needed to complete plans, gain official and public acceptance, and complete financing and construction.

The State water resources board has taken the main responsibility for determining the availability and quantity of ground water, as the State board of health has for determining the chemical quality. Information on hydrology has been included in an annual program of inservice training for consulting sanitary engineers with some consequent changes in design practice.

A critical element in the program, he said, has been the periodic appraisal of water systems by board engineers, who follow their reports with appearances before the governing bodies of the cities, to explain the deficiencies and to urge their correction. Supporting this pro-

gram, the League of Municipalities in Kansas prints annual board of health tabulations of municipal waterworks data, including capacities and daily demand.

Identifies Guilty Syndet Agents

The main source of the public health problems created by the Nation's current annual consumption of 3.8 billion pounds of synthetic detergents was identified by Jesse M. Cohen, Robert A. Taft Sanitary Engineering Center, Public Health Service. He also reported that active research on new forms of detergents offers a possible release from the present difficulties.

Surfactants of the ABS-type, the most common cleansing agents of today's syndets, were specified as responsible for some water and sewage plant problems which have emerged in recent years. Among the problems he mentioned are frothing in aeration tanks and outfall lines in sewage treatment plants, ABS residues in sewage effluents, additional phosphate nutrient for growths of algae with their attendant problems, and contamination of ground water and drinking water with ABS residues. Many of these effects, he said, are due to one outstanding difference be-

**Decrease in concentration of detergents in river water
at 18°-19° C.**

tween soap, almost the exclusive cleaner 20 years ago, and the syndets currently in use.

Whereas soaps are easily decomposed by biological activity, the common syndets employing ABS-type surfactants resist biological decomposition. For this reason, he explained, syndets can survive, at least in part, sewage treatment, natural biological oxidation processes in streams and ground water travel to appear in varying reduced concentrations in drinking water. An early evidence of detergent pollution is foaming of tapwater, which occurs with concentrations as low as 0.8 ppm.

All detergent molecules, both soap and syndet, contain a long hydrocarbon chain. In soaps, which are derived from fatty acids, and in syndets derived from fatty acids or alcohol, the hydrocarbon chains are readily decomposed to smaller fragments and eventually to carbon dioxide and water.

The raw material for the more commonly used ABS-type surfactants is propylene, which is obtained from petroleum. The processing of propylene for these surfactants yields a detergent molecule containing an alkyl group which is a saturated, highly branched hydrocarbon. More important, this hydrocarbon chain contains a quaternary carbon atom. Extensive biochemical studies have shown that this chemical structure of ABS prevents microbial oxidation and makes it possible for the ABS molecule to persist in biologically active solutions like sewage or streams.

The accompanying chart illustrates the rates at which the various types of surfactants are decomposed in river water. Compounds A and B, derived from fatty acid and straight-chain hydrocarbons, are biologically decomposed in 2 to 4 days. Compounds C and D, the ABS-type containing an alkyl group of petroleum origin, persist for longer than 20 days, which is long enough for this contaminated water to arrive at a water treatment plant in the water supply.

Up to the present time, there is no economical way of removing surfactant material from drinking water. Common water treatment processes, such as chlorination, chemical coagulation, and rapid sand filtration, reduce surfactant concentrations by either insignificant amounts or not at all. Current research is therefore directed primarily toward removal at the sewage treatment plant.

Research in another direction is of equal importance. Consideration has been given by manufacturers to development of other compounds equal in cleansing properties to the present surfactants but different in that they would be vulnerable to microbiological degradation.

Private Swimming Pool Standards Given

Swimming pools in the backyard and their public health implications were discussed by Edward L. Stockton, municipal public health engineer, when he reported on standards of construction and operation of privately owned pools, as recently established in Grand Rapids, Mich.

Stockton stated that a simple system of requirements has a better chance to achieve satisfactory operations. Main requirements are a 4-foot fence surrounding the pool; a minimum of two inlets on rectangular pools, more on free-form pools; complete replenishment of water within every 12 hours, with rate of filtration not to exceed 3 gallons per square foot per day; and uniform application of chlorine to maintain a constant residual of between 0.4 and 0.6 parts per million.

Most pools are either 16 by 36 feet or 20 by 40 feet in size, he continued. Diatomite filters are used on all newer pools, and skimmers instead of scum gutters. Pressure gauges or rate of flow gauges are not required.

Chlorination machines are permitted, Stockton said, adding that most people use chlorine tablets. When liquid hypochlorite is used, it is suggested that one-half cup of

Calgon per 15 gallons of solution be added to prevent clogging and aid in pH control.

Water in all pools in Grand Rapids was sampled twice in 1958 and 1959. Thirty percent of these samples were unsatisfactory on bacteria plate count and 26 percent by coliform index, mainly as a result of an insufficient period of filtration. Samples of water compared with chlorine residuals at time of sampling showed approximately the same percentage of unsatisfactory results.

Examples of difficulties were cited by Stockton. Many pools are not operated 12 hours or longer. As a result, he said, it has been impossible to enforce the requirement of replenishment of water every 12 hours. Many operators are not aware, he added, that diatomite filters must be recharged when a pool is reopened.

Stockton also mentioned instances of plastic lines connected directly to the sewer for backwashing operations. He said closer field inspection will be necessary to prevent the installation of such cross connections.

Adoption of a city ordinance is essential, Stockton stated. He recommended a reasonable attitude in stating pool requirements, emphasizing that these requirements should have broad functional outlines rather than being confined to specific details. Because of the rapidly changing picture in pool installations, specific standards tend to halt full use by the public of new and better designs.

Pay-as-You-Grow Sewer System

A complete suburban sewer and sewage treatment system, financed as easily as a piecemeal program, with an eye to the needs of the next generation, was described by Peter Homack, consulting engineer of Elson T. Killam Associates, Inc., Millburn, N.J.

Square in the path of a growing urban population, the township of Berkeley Heights, N.J., in 1955 confronted the familiar issue: to be or not to be dotted with septic tanks. Despite a low population density, with fewer than 1,000 homes in an area of 6.3 square miles, the township found its subsurface disposal systems, including septic tanks, tile fields, and cesspools, were a menace to families on the lower slopes. Impervious soil, traprock, and a high table of ground water gave little opportunity for remnants of domesticity to sink harmlessly away.

Builders, eager to add to the value of real estate in the township, were disappointed to learn that their plans for installing more individual disposal systems, under a tightened State health code, would be disapproved. As they presented alternative proposals for sewage treatment plants for small neighborhoods, the so-called package plants, township authorities began to look into the possibility of a central system.

The builders agreed to a prepayment assessment of \$350 per house projected. A capital improvement fund of the township contained another \$150,000. The builders also planned to install at their own expense lateral and interceptor sewers passing through their properties. As a result, nearly half of the cost of the system was supported by builders of 112 new homes. The balance was financed with bonds backed by the credit of the township.

Construction started in 1956. The treatment plant began operation the following year. Since then, 300 homes per year have been connected to the system, and neighboring communities are asking for an opportunity to tie in. It is probable that with revenues from other townships, and a local sewer service charge of \$20 per home connected to the system, the income from the plant will exceed its operating and carrying charges.

With extension of the sewer system to 80 percent of the homes in the township, 1,600 units will be connected. The total cost of the sys-

tem, including lines paid for by builders, is about \$3 million.

The design, however, provides for an eventual population of at least 20,000. The sewers are large enough to be adequate for the township population 40 years in the future, and the treatment plant is meant to serve without expansion for about 15 years.

The annual interest and amortization charge, said Homack, is no more than it would have cost to undertake a limited sewer construction program, year by year.

Package Plants Evaluated

Package plants are here to stay is the conclusion of John E. Kiker, Jr., professor of civil engineering at the University of Florida. But he believes many improvements in design and operation are necessary.

A study of such plants, in comparison with conventional sewage treatment plants, was undertaken in Florida in 1958, under the general sponsorship of David B. Lee, director of the bureau of sanitary engineering of the State board of health, with collaboration of the university and the Public Health Service.

Under far from ideal conditions, the investigation succeeded at least in improving its methods of evaluation, and in developing information which led Kiker to draw certain conclusions, as follows:

- Effective results with package plants, some of which were excellent, depend on the quality of maintenance and operation. For comparable results, conventional plants need less attention than the others.

- There is as yet no such thing as a "maintenance free" package plant. No mechanical aeration plant has "only simple mechanical components." Troubleshooters ought to be available wherever such plants are installed.

- All plants should have convenient and accessible flow measuring devices, preferably with a totalizing meter or recording device, as

well as electric power meters, if costs and performance are to be appraised.

- Plants which do not have adequate laboratory facilities, or sanitary facilities, including showers for personnel, are seldom operated properly.

(A student, John E. Hagan III, who shared in the investigation, commented, "Lack of laboratory facilities greatly hinders the operator. There is always a tendency to leave undone anything which seems inconvenient or difficult; also, where the operator has many other duties, the time element may become important. Convenient laboratory facilities will greatly reduce the tendency to overlook routine lab work.")

- Composite daytime samples are more suitable for evaluation of package plant operations than those taken around the clock.

- Designers of sewage treatment plants would do a better job if they gave more consideration to operating tasks. Many plants are designed without provision for steps or sampling facilities. Other deficiencies, sometimes hazardous, are an absence of handrails around tanks, inadequate walks, open channels, and insufficient lighting.

- Plants should be at least 500 feet away from the nearest residence, as a protection against noise and odor.

- Air compressors should be provided in duplicate, as insurance against a failure.

Further studies of cost, design, and operation are recommended by Kiker.

Design for Burning Urged for Refuse

Nothing is wrong with incineration that proper design and operation cannot cure, according to Glen H. Abplanalp and Junius W. Stephenson, consulting engineers with Haydens and Emerson, New York City.

Tracing the history of incineration, they put much of the responsibility for failures on the tendency to

accept manufacturers' designs and ratings, rather than designs and ratings independently determined. Only Connecticut, they said, has set State criteria which incinerators must meet, and they said none of the burners installed in recent years in that State are known to be unsatisfactory.

A technological change which encourages incineration, they said, is the increase in the marketing of trimmed food. While the packers sell the stems and peellings and other trim for processing as fertilizers, the ratio of garbage to rubbish in domestic refuse has declined from 50-50 to 10-90. As a result, modern refuse is lighter, drier, bulkier, and more combustible than in the past, with the result that, in operating an incinerator today, the task is often one of holding temperatures within reasonable limits while maintaining desired burning rates.

States should give attention to incineration, they said, because the supply of land suitable for fill operations is limited. Nevertheless, only Connecticut, Florida, and New Jersey require that incinerators be designed by qualified engineers. Only Hawaii, New Jersey, and Oregon have established specific regulations for incinerator operation, but in each case the regulations are based entirely on air pollution standards. The authors recommended that standards apply also to storage, handling, safety, residue disposal, and general sanitation.

The consensus of State officials, they said, favors closer State control over all phases of refuse disposal, with detailed regulations and power of enforcement. The authors concluded that health departments logically should guide refuse disposal in a manner comparable to their present guidance of water and sewage treatment.

Landfills Replace Jersey Dumps

The figures tell the story of New Jersey's achievement in developing sanitary methods of refuse and gar-

bage disposal, under chapter 8 of the State Sanitary Code, which became effective July 1, 1958, according to Alfred H. Fletcher, director of environmental health, and John Zemlausk, principal sanitarian, of the State health department.

The number of sanitary landfills in the State at that time was 33, serving 149 municipalities with 19 percent of the population. (Another 16 percent were served by 18 incinerators.)

Fifteen months later, 100 sanitary landfills served 299 municipalities, with 44 percent of the State population. (The 16 incinerators still in operation then served 12 percent.)

First move in the change came with the recommendation of a 1953 advisory committee, proposing legislation to outlaw open dumps and to establish a code for sanitary landfills.

While the program still has room to advance, the experience to date is useful to the remaining municipalities of the 567 subject to the code.

Two landfills charge for disposal by weight, at rates ranging from \$1 to \$3 a ton.

Others charge from 10 to 30 cents per cubic yard.

Still others charge \$2 per truck load, or \$1 to \$1.25 per person per year. A few charge \$1.25 to \$3.50 per family.

Hauling distances run as high as 28 miles, but no municipality is more than 10 miles distant, in a beeline, from a sanitary landfill.

The authors find that landfills are less costly to operate than the open dumps they are replacing, in part because vehicles suffer less damage on the compacted terrain. Another economy is that landfills do not require the waterlines needed to control spontaneous fires in dumps, or policing, or the legal services which surround a public nuisance.

Most collection and disposal of refuse in the State begins with a contract between an individual household and a private contractor. This system characterizes suburban settlement. The greatest volume of refuse is disposed of under contract between a municipality and private enterprise, obtained by competitive bidding. The least prevalent method is municipal ownership and operation of the system.

Air Pollution . . .

Atmospheric Pollution Public Worry No. 5

Air pollution ranked fifth in seriousness among 10 selected community problems in a survey of public awareness in Erie County, N.Y., reported Dr. Preston Valien, former technical consultant, New York State Air Pollution Control Board, Albany. Outranking air pollution, according to respondents, were unemployment, automobile accidents, juvenile delinquency, and alcoholism. But air pollution outranked factory accidents, contagious diseases and epidemics, sewage disposal, exposure to radiation, and home accidents.

A probability sample of 462 households in Buffalo and 481 in the county, with respondents classified by sex, educational level, socioeconomic status, and residential areas, was surveyed, Valien explained.

Slightly more women than men viewed air pollution as a serious problem. Air pollution was designated as "very serious" by 19 percent of the group, "somewhat serious" by 16 percent, and the rest considered it "not serious" or didn't know.

By educational level, the percentage of respondents describing air pollution as "not serious" ranged from 47 percent of those completing

eight grades or less of schooling to 69 percent of those with some college training. Seventeen percent of those in the lowest educational category and 25 percent of those at the bottom fourth of the socioeconomic scale answered "don't know" concerning the seriousness of the air pollution problem, said Valien.

Only 53 percent of those questioned thought air pollution was definitely a public health matter, although nearly 80 percent classified control of contagious diseases and epidemics and sewage disposal as public health concerns. The concept of air pollution as a public health matter did not vary on the socioeconomic scale or by rental area, but it was recognized more frequently as educational level went up.

The interviewees were asked to indicate any physical discomforts and property damages which may have resulted from polluted air. Unpleasant odors were named by 42 percent of the Buffalo residents and 29 percent of the county residents. Coughing, sneezing, and difficulty in breathing were listed by 10 to 13 percent of the Buffalo respondents.

Property damages from air pollution, reported by 59 percent of those in low rental residential areas and 48 percent in the high rental areas, were listed most frequently as dirty house paint, dirt on the family wash, and damaged car paint, the author said.

Air pollution had a bad effect on people's health, 87.5 percent of the group believed, was bad for real estate values, thought 80 percent, and had a bad effect on business in general, 60 percent felt.

Asked to name important sources of polluted air, 80 percent named factories; 61 percent, buses; 53 percent, city dumps; 45 percent, automobiles; and 11 percent, homes. In investigating how the respondents' actions contributed to air pollution, approximately 30 percent said they sometimes burned leaves, papers, or trash at home, and 60 percent of these had done so within the previous week.

Forty-five percent of the group said they had read or heard something recently about air pollution, most often that it was a problem in other States, Valien said. Asked to give sources they would depend on for information about air pollution, 41 percent preferred newspapers; 21 percent, television; 18 percent, radio; and 17 percent, pamphlets. However, these responses varied according to educational level, with pamphlets named primarily by the college group, and television by the less educated. These preferences for a specific medium as an information source have important implications in educating the public concerning air pollution and other aspects of health information, said Valien.

Mortality Data Reflects Air Pollution

Use mortality data to study possible health effects of air pollution, suggested John C. Rumford, public health analyst, Air Pollution Medical Branch, Public Health Service.

He outlined simple procedures which local health agencies can employ to compare intra-area and temporal variations in mortality to variations in indexes of air pollution and other environmental factors.

Intra-area or intracity investigations are based on the assumption that if there is an association between manifestations of air pollution and mortality, residents in areas of high pollution should have higher mortality rates. Because these areas usually have other adverse environmental conditions, the total socioeconomic complex of an area must be considered, he said.

In these analyses, he explained, the study area is usually subdivided into components such as census tracts, community areas, economic areas, or health districts with available population statistics. The subdivisions are then characterized by manifestations of air pollution and other factors such as income, hous-

ing, education, and racial composition.

Rumford cited, as an example, a study of Philadelphia health districts. Preliminary results suggested that pneumonia and arteriosclerotic heart disease were apparently equally influenced by both variation in dustfall and socioeconomic variables. Variation in chronic rheumatic heart mortality was more strongly related to dustfall than to any of the indexes of socioeconomic conditions. Variations in mortality for other diseases of the heart and tuberculosis were more closely associated to socioeconomic indexes than to dustfall. Such relationships should be studied further to see if a true association has been divulged, said Rumford.

He described another intra-area study, made in Chicago, to develop and test methods applicable to micro-units of a large metropolitan area. The study population was limited to white females, since residence in a particular census tract was of prime importance. Three approaches were used. In the first, mortality variations among residents of manufacturing and nonmanufacturing areas of Chicago were compared. The results suggested that those living in nearly all manufacturing areas experienced higher mortality than residents of nonmanufacturing areas.

The second approach was to compare mortality experience among residents who lived 1 mile from a large primary metals plant with that of residents living from 1 to 2 miles from the plant. In census tracts less than 1 mile away mortality was more than 30 percent higher than in the tracts 1 to 2 miles away.

The third approach was to investigate residential mortality variations in census tracts less than 1 mile from the plant in relation to prevalent wind direction. Results indicated that standardized mortality rates were highest for those living in quadrants more frequently in the path of winds blowing across the plant. Socioeconomic conditions of the area apparently contributed little to mortality variations.

In the second major category of investigations, the temporal study, it is assumed that mortality rates for selected diseases should increase or decrease with abnormal increases or decreases in actual measurements of air pollution or a manifestation of pollution, he said.

Methods used in temporal studies vary with the geographic and time units chosen. If an entire city is used, abrupt departures from the normal levels of air pollution are plotted graphically with mortality incidence. Weather factors such as maximum and minimum air temperature, rainfall, snowfall, and humidity are plotted as third variables. Usually, positive fluctuations occur in all variables when threshold levels of air pollution are reached. Therefore, the difficulty is in determining which variable fluctuated more directly with mortality.

For example, when an extreme high-pressure air mass over New York City created stagnant atmospheric conditions for a 4-day period in October 1956, cardiovascular mortality increased sharply. Graphing of the variables revealed a 2-day lag between temperature and mortality peaks in contrast to simultaneous peaks in dust count and mortality.

Temporal studies have also been done during prolonged steel strikes. Admittedly, these investigations suffer from handicaps such as a population too small for significance tests of a small percentage effect and extremely limited air pollution data. Also, there are numerous variables and conflicting factors in studies of this type.

In spite of these reservations, the Air Pollution Medical Branch hopes such studies will assist, guide, and stimulate air pollution-health studies, Rumford declared.

Effects of Donora Air Continue Uncertain

Persons who reported acute illness at the time of the 1948 air pollution episode in Donora, Pa., have demon-

strated subsequently higher mortality and prevalence of illness than other persons living in the community at that time, according to Antonio Ciocco and Donovan J. Thompson of the department of biostatistics, graduate school of public health, University of Pittsburgh, reporting on a followup study made 8½ years after the episode.

Furthermore, persons who complained of more severe acute illness in 1948 demonstrate greater subsequent morbidity and mortality than persons with mild complaints, they said. There is some evidence that this greater morbidity and mortality is related to the cardiorespiratory system. Ciocco and Thompson reported. However, they cautioned, "Before these facts are hastily interpreted a more searching analysis is required."

They pointed out that many smog victims in Donora had reported chronic cardiorespiratory illness before 1948. If their histories are disregarded, the differences in the rates of illness and death among those acutely ill during the smog and those who did not experience illness then are narrower.

The 1957 data showed that even persons who denied a history of heart disease prior to October 1948 but became ill during the smog episode have had a higher subsequent morbidity rate than persons of the same age and sex who did not become ill. Mortality was also higher, although the difference is less marked. At face value, they said, it would seem that subsequent health experience is related to complaints first arising during the 1948 episode. However, there is often considerable underreporting of impairments in interview surveys, Ciocco and Thompson pointed out. If any significant amount of such understating of previous illness did occur in 1948, the 1957 findings would mean that discomforts of the smog episode only served to bring out or emphasize existing impairments.

The Public Health Service community survey made shortly after the October 1948 acute episode, covered

a systematic one-third sample of Donora's households, involving 4,092 residents. Data were obtained on:

- Age, sex, occupation, residence.
- Past experience of asthma, sinusitis, heart disease, chronic bronchitis, tuberculosis.
- The occurrence of cough, nausea, vomiting, headache, and smarting of the eyes during the October pollution episode.
- The persistence of these symptoms.
- Physician and hospital service treating the ailments.

For their 1957 followup studies, Ciocco and Thompson were able to trace slightly more than 99 percent of the original 1948 group by personal interview and mailed questionnaires.

Troublesome Questions

Ciocco and Thompson had hoped to obtain an indication of the relative significance of the acute episode and chronic exposure over the years. However, no such clear relationship between illness and environmental variables, such as period of residence in the Donora environment, place of residence in the community, occupation and place of work, has been established by the study.

The findings of the study, they said, raise three central questions:

1. To what extent is the subsequent health experience of those persons who became ill during the 1948 smog related to complaints first arising during the episode or to complaints present before the episode?
2. To what extent is the greater morbidity and mortality a direct consequence of short-term massive exposure to air pollutants, or continued exposure both prior and subsequent to the episode, or a combination of the two types of exposure?
3. To what extent are the manifestations of sickness specifically related to the particular pollutants in the Donora air?

Although some of the data do point to some effects on the cardiorespiratory system, they do not provide the means for relating particular pollutants to specific systems. The lack

of knowledge as to what syndromes appear most pertinent for air pollution-health studies is vexing to all researchers in this area, Cioceo and Thompson said. The efforts and experience of many investigators will be required before the relation of continued exposure to airborne pollutants and health in large population groups is clear, they declared.

Air Pollution Control Tasks Lie Ahead

Air pollution control has scored remarkable gains in Pittsburgh and Allegheny County but much remains to be done, according to Lee Schreiber, Jr., acting chief, Bureau of Air Pollution Control, John J. Grove, assistant director, Allegheny Conference on Community Development, and Dr. Herbert R. Domke, director, Allegheny County Health Department.

They described the industrial, civic, and social redevelopment that has accompanied effective smoke control and indicated future trends in the task of insuring cleaner air.

Continuing public and industrial support, as well as technological advances are necessary if gains are to be extended to pollutants other than smoke. Planning for the next stages requires accurate appraisal of the kind, quantity, and sources of pollutants, better techniques for control at the source, and precise, enforceable definition of control techniques in legal form in ordinances, they maintained.

Plans for control need to include the two broad categories of sources, industrial (manufacturing, service, and transportation industries) and public (automobile operation, home heating, burning trash, and other similar actions). Both types of sources, they said, contribute significantly to atmospheric contamination.

They cited R. S. Scorer's estimate that home heating and automobile and truck use caused 90.5 percent of the annual \$750 million worth of damages from air pollutants in Great Britain. This estimate, while not

directly applicable to Pittsburgh, they stated, demonstrates the need for caution in pointing to industrial sources as the principal offenders.

In Pittsburgh, the great reduction in smoke pollution from 1946 to 1959 was caused by the shift from coal to gas in heating homes and the shift from coal to diesel oil in transportation. The city's experience also demonstrates that, while total fuel consumption increased during those 13 years, smoke and dustfall have decreased.

The cost of control can be figured in dollars, the authors said, but it is sometimes difficult to put a price tag on irritation, nuisance, and property damage that result from polluted air. In Pittsburgh, heating an average home with approved fuels adds approximately \$22.75 to the yearly heating bill. Installing collection equipment in one industrial

source, an open hearth furnace, costs \$600,000, and to operate the equipment, \$100,000 a year. In Allegheny County, 12 out of 102 such furnaces have been so equipped.

Commenting on trends in air pollution control codes and ordinances, the authors noted that existing codes exhibit wide variations in the permissible smoke emission and permissible rates of discharge of solids. Some recent ordinances also specify permissible emission rate for certain types of process equipment. And some ordinances include requirements directed at specific industries, such as rendering, drycleaning, lann-dering, and asphalt plants.

The direct rewards of eliminating smoke are great, said the authors, but the indirect results of clean air—the restoration of civic pride, courage and determination in Pittsburgh—can be almost incalculable.

Food and Nutrition . . .

Dietitians Go in Where Chemists Cannot Tread

Methods of measuring what people eat, in relation to their health, were reviewed in two papers: one by Marjorie Cantoni, nutrition consultant, Dr. Ralph S. Paffenbarger, epidemiologist, and Dean E. Krueger, research analyst, all of the Public Health Service, and the other by Dr. Marjorie Grant Whiting, nutritionist, Public Health Service, and Dr. Ruth Leverton, associate director, Institute of Home Economics, U.S. Department of Agriculture.

The first dealt entirely with the nutrition phase of studies related to cardiovascular diseases. Ideally, the authors explained, the relation of diet to cardiovascular disease conditions should be appraised by lifetime studies of cohorts. Thus far methods for assessing eating habits have limited investigators to taking histories from individuals concern-

ing immediate or recent food patterns.

Such studies either test a specific hypothesis, such as the relation of fat to levels of serum lipids, or they analyze a collection of data about diet and disease in the search for possible broad associations. Comparison of the dietary habits of persons with or without clinical disease can provide only indirect evidence, and this kind of inferential reasoning comprises the epidemiological method for the study of a disease.

Snapshot, Flashback, and Movie

Three types of comparisons are currently in use: the snapshot, flashback, and movie methods. Snapshot (cross sectional) studies compare diet of a diseased population with that of a disease-free population at a given point in time. Flashback (retrospective) studies seek information from such groups on their diets as far back as possible. Motion picture (prospective) studies follow a

Comparison of results from concurrent calculation and analysis of weighed diets

¹ Cases taken from available Canadian, British, and United States literature; a total of 31 studies.

group with specific diet habits for comparison with a group without specific diet habits, well into the future with an eye to development of pathological conditions.

In all such studies, it would be appropriate to employ standardized measurements and accurate classification of individuals as to their diet and disease status, the authors observed, with a note of regret for difficulties in obtaining ideals. But even without precise standards, they reported useful information was obtained from personal interviews and clinical observations.

The accuracy of information about diet is checked, sometimes by questioning other members of a family and sometimes by repeating the questions at other times or in other forms. Information from interviews is also compared with information obtained by recording, and sometimes weighing and analyzing, food as served. Recall of a meal, incidentally, is easier, one group of investigators has found, if the first question asks what meat was served.

Test Tube vs. Punchcard

Both papers commented on the difficulty of accurately appraising the nutritional composition of food intake. Reliability of dietary information was the major topic of the paper by Whiting and Leverton.

A chicken and noodle dinner, they observed, might be a delight to a gourmet, but to a nutritionist it is a big question mark. As any house-

wife knows, the relation of chicken to noodle is not constant. When such a meal is reported to a nutritionist, it is possible only to speculate how much was protein and how much was carbohydrate, how much fat was in the chicken, and the quantity and characteristics of additional fat in the total dish.

As a check on the reliability of information concerning food intake which may be reported verbally or in writing, composites representing the day's intake can be analyzed in the laboratory for nutrient content. Even this appraisal of diet by chemical analysis, they said, has its own shortcomings, apart from the cost.

Subtle chemical changes in food may occur between the time of collection and analysis. And certain combinations of food continue to defy separation into components significant to nutrition. Also, biochemical studies, it was noted, suggest that perhaps it is not the total intake that affects metabolism so much as combinations of foods and even the order in which they are consumed. Even so, laboratory analysis, they asserted, is the most reliable method of describing the nutritive value of a meal.

Tables of average food values, like all other averages, they pointed out, cover a multitude of variables. Among those they mentioned were the effects of differences due to species, season, soil, climate, storage, and processing, as well as variations in the recipe for hash.

The comparison of the two meth-

ods of analyzing diets, one obtained by laboratory analysis and the other by calculating values of weighed portions of food, was based on available studies by various investigators in Britain, Canada, and the United States. In a bare majority of the 300-odd cases, values obtained by calculation came within 10 percent of agreement with values obtained by laboratory analysis, with respect to protein and calories. With respect to fats, such agreement was achieved in only one-fourth of the cases (see table); in nearly half the cases, calculated results were higher than laboratory results by more than 10 percent. A major error in fat calculation, they believe, is that tables of food values have failed to allow sufficiently for the amount of fat which is trimmed or melted out of meat before it is served.

For epidemiological investigations, the amount of variation found between these two methods of determining nutrient value casts doubt on the significance of differences between any two studies of less than 20 percent in the intake of calories and protein and of differences of less than 30 percent in the intake of fat.

Food Industry Tries Self-Inspection

Within the next few years, the great majority of food operators in major cities of this country will be constructively cooperating with local health departments in establishing

and maintaining proper sanitation practices, declared Max J. Kleiner and Samuel A. Coleman, directors of the Food Sanitation Consultant Service, New York City.

However, the attainment of this objective will require sustained and continued emphasis on public health education and insistence on responsible self-inspection, they said.

Self-inspection regulations grew out of action taken some years ago by forward-looking members of the food industry who employed sanitation consultants and took part in public health measures designed to reduce insanitary practices.

Some of the self-inspection codes, drafted by city and State health departments, stress only good housekeeping. Others prescribe a full sanitation program involving education of employees; personal hygiene and food-handling practices; menu analysis and food technology, including time and temperature studies; food poisoning and quality control, including chemical and bacterial analyses; rodent and insect surveys; food storage programs; maintenance and equipment information; and standard requirements concerning ventilation, safety, and water supply and sewage in rural and suburban areas.

Kleiner and Coleman divided the food industry into three groups in evaluating the extent and quality of current compliance with regulations.

Group 1 consists largely of food chains, hotels, food processors, and the majority of large restaurants. Its members give careful attention to the self-inspection program and seek to advance it. They obtain adequate equipment, competent help with layout problems, and advance approval of health departments for their plans and practices.

Group 2 is numerically the largest but in meals served does not approach the volume of food handled by those in group 1. Members of this group do not institute their own inspection programs where no official requirement for self-inspection exists, since they consider it an

unnecessary financial burden, according to Kleiner and Coleman. Where self-inspection is required, they give token compliance, usually at lowest possible cost and with stress on housekeeping alone, Kleiner and Coleman said.

Group 3 is made up almost entirely of small and marginal operators who, according to Kleiner and Coleman, see self-inspection valuable only as a protective device to keep health department inspectors out of their establishments. Their observation of regulations usually consists of jotting a few minor items in a notebook, whether the conditions noted exist or not, and then dating their notes to appear they have made an inspection, Kleiner and Coleman charged.

Glamorous Food Frauds Shade Dull Food Facts

Through plausible peddlers of pseudoscience, the public is far more influenced by misinformation about diet than by the sober truth which nutritionists and physicians have to offer, according to Dr. Martha F. Trulson, associate professor of nutrition at the Harvard School of Public Health. The money wasted

on food frauds, she said, is estimated at a billion dollars a year.

Citing examples of fraud and deception, with immeasurable effects on the family health, Trulson asserted a need for encouraging scientific authorities to provide honest information for the mass media, with or without the collaboration of professional writers.

She noted that one supermarket on the west coast employs a dietitian to answer questions about meal planning and the food values of specific products in an effort to offset misinformation notoriously rampant in that region.

Other informational steps recommended by Trulson include: appraisal of the economic and physical cost of food frauds; integration of nutritional information in various aspects of the school curriculum; basic instruction in nutrition at teacher's college and continuing guidance to teachers; publication of satisfactory textbooks on nutrition for a variety of grade levels; and utilization of nutritional information available from reputable sources, including materials available from the American Medical Association, the American Dietetic Association, the Food and Drug Administration, and the National Better Business Bureau.

Medical Care . . .

Medical Care Held Department Duty

Health officers were challenged by Dr. Lester Breslow, chief of the bureau of chronic diseases, California State Department of Public Health, to assume leadership in applying medical advances toward improvement of public health and to assert their competence in the field of medical care.

In voicing the challenge, he asserted that medical care has clearly become one of the most effective means to advance the health of the

people, which health officers must take into account no less than sanitation, education, and other programs. The competence of health officers in medical planning and administration, and their training and experience, suit them peculiarly for service in this field, he added.

What should the health officer do about medical care? Breslow suggested a realistic assessment of the value of medical care to public health, mentioning the analyses and examples given in the 1958 report of the chairman of the APHA Technical Development Board as possi-

ble guidelines. He also urged health officers to seek technical advice on questions of medical economics, saying resolution of these issues will obviously influence the timing, nature, and scope of further governmental effort.

Appropriate action is the next step, Breslow continued. The aim should be to assure medical care of adequate quality and quantity to all segments of the population the health officer serves. In attaining this goal, the health officer, with epidemiological training, prevention as a traditional background, a primary interest in public health, and experience in community organization, is the ideal person to lead much needed investigation into the medical care needs of the whole population, the extent and quality of present services, and in the development and maintenance of standards.

Administrative responsibility for the expanding public medical care programs is being entrusted to agencies of State and local governments other than health departments, Breslow said in his concluding remarks, adding that the time has arrived for a critical review of the question by health officers.

Ambulant Patient Costs Ambiguous

An evaluation of the costs of comprehensive medical care to ambulant patients reveals the ambiguities inherent in the concept of such costs, according to Dr. George G. Reader and Miss Margaret Oleneki of the New York Hospital, Cornell Medical Center.

Costs are directly affected by policy, they said. If the highest level of health is sought, thorough and complete medical care may be most economical in the long run, to the extent that prevention of disease is cheaper than cure and early treatment is usually more economical than late, they explained. At the same time, the cost of thorough examination may be all out of proportion to the need, they added.

As Iago Galdston once wrote, to negative diagnosis there is no end. Moreover, a lower standard of health and care may present immediate economies which are expensive in the long run. For example, they described a patient treated summarily for an itch and epigastric pain at a cost of a few dollars, in contrast to the cost of a complete workup which might have discovered a cancerous condition.

They concluded therefore that costs depend on the level of care proposed, and the ingredients essential to a given program of care. Given these variables, they feel it is possible to determine the cost per patient or patient group.

The authors examined the charts of 719 patients, a cross section of the population of the General Medical Clinic of the New York Hospital, for 1 year. Costs of visits and services were tabulated both in terms of charges paid by the patients and expense to the hospital.

It was found that 18 percent of the patients paid nothing for services and 2 percent paid over \$100. The median cost to patients was \$13.

Only 16 percent of the patients cost the hospital less than \$10 and 11 percent incurred an expense above \$100. The median expense to the hospital was \$38.

Visits to a physician accounted for the largest single share of outpatient cost, but X-rays and laboratory tests were the most expensive items.

Cardiovascular disease and diabetes create costs above average. Patients with syphilis are the least expensive. Psychoneurosis is associated with a fairly large initial expense until serious disease is ruled out but is thereafter below average in cost.

Costs also increase with the age of the patient, more so for men than for women, but it is hard to say which factor, increasing age or certain diagnoses associated with age, contribute more to expense.

An inverse relationship was found between costs incurred and eco-

nomie status; the poorer patients incur the higher costs.

No general conclusion is warranted from these findings, the authors stated, but they feel that clues for further study are clearly discernible.

Blues Singers Call Doctors

Psychological reactions perceived as bodily symptoms accounted for 84 percent of the initial visits to the Massachusetts General Hospital medical clinic, according to an analysis of a random sample of 101 such visits studied by doctors on the staff.

The authors, Dr. John D. Stoeckle, Dr. Gerald E. Davidson, and Dr. Jerome L. Weinberger, are all associated with Harvard Medical School as well as Massachusetts General.

This part of a continuing study of psychological factors in illness examined specifically the frequency of requests for medical care when depression following traumatic loss is present. All patients selected for study were visiting the clinic for the first time or for the first time in 1 year. They were considered ill and were referred by community physicians, by other clinics, by the emergency service, or were self-referred. All were paying patients, and no self-designated psychiatric patients were included.

Four questions were asked:

- Were symptoms related to bodily disease or was a psychological reaction presented?
- What identifiable bodily disease was present?
- What events in the patient's life preceded illness and the decision to consult a doctor?
- What were the specific psychological reactions to these events and what relationship did they have to the illness and the decision to consult a doctor?

Psychological reactions were classified as depression, hypochondriacal, obsessional, anxiety, and conversion.

More than 50 percent of both men and women had a reaction of depres-

sion. Of the 85 patients with psychological reactions, 73 reported onset of symptoms coincided with events of traumatic loss, such as separations, real or threatened bodily injury, changes in family or job status, or death. There were no differences between men and women in type or frequency of precipitating events.

Bodily disease was found in 43 percent of all patients, and in 32 percent of the patients with psychological reactions.

This proportion of somatic illness is the same as first reported from this clinic in 1905 by Richard Cabot. The authors emphasized that both organic and psychological illness occur at the same time, but the reason for coming to the clinic was most commonly psychological.

California Physicians Sign Medical Care Contracts

The formation and operation of the San Joaquin Foundation for Medical Care were described by Mrs. Goldie Krantz, secretary of the joint welfare fund of the International Longshoremen's and Warehousemen's Union and the Pacific Maritime Association.

The 218 members of the San Joaquin Medical Society, representing 92 percent of the physicians in the county, incorporated as a foundation in 1954. Today, foundation membership includes 98 percent of the physicians in San Joaquin and two adjacent counties, Tuolumne and Stanislaus, Krantz said. The stated goals were formulation of a basis for group prepayment of medical care, an individual and family prepayment program, and the study of methods to present the desirable features of such a prepayment program to other ordinarily intelligible groups in the population. In addition, the concept was a prior countywide fee agreement based on and reflecting prevailing medical practices in the area.

The foundation is governed by a board of directors which also serves as the medical services committee of

the county medical society. Any licensed physician and member in good standing of the county medical society is eligible to apply for election to participating membership in the foundation.

Krantz said that, to assure positive acceptance by the physicians and to guard against apathy, the doctors reaffirm their membership each year by signing a contract.

The foundation, according to Krantz, uses eight insurance companies, including the California Physicians Service, to underwrite medical care programs covering 20,000 people, out of a 200,000 population. The original fee schedule has been revised by setting up three fee schedules related to the income level of a given group.

In explaining the union's decision to contract directly with the foundation for medical care, Krantz emphasized the noninsurable services given by such a program. "We worked jointly with the medical society to establish our own actuarial concepts and at the same time satisfied their moral need to use the average income of the men in the group. The foundation took the risk and, in a few instances, the losses when our educated guesses on premiums were not accurate."

In citing the advantages of medical care as supplied by the foundation, Krantz said physicians are no longer bound by actuarial concepts that may have lost their applicability. Continuity of care by referral out of the area is assured, as referrals are coordinated by the foundation.

Krantz compared the San Joaquin experience with the Kaiser Foundation Health Plan in San Francisco. Hospital days per case in San Francisco were 13.7 per man for the 1957-58 year, 7.4 in San Joaquin, an increase of 11 percent for Kaiser and a decrease of 12.5 percent for San Joaquin. Office calls per man were 3.9 for Kaiser and 3.7 for San Joaquin, a decrease of 2 percent for Kaiser and a 15 percent increase for San Joaquin.

She said there are now four founda-

tion programs operating in 14 counties in California and 6 more county medical societies have established foundations. These programs were said to vary as to local needs and reflect local practices. In some programs, patients use credit cards provided by a local banking system.

Farmer in the Dell The Doc Picks a Doc

How does a physician select medical care for himself and his family? Dr. Milton C. Maloney, Dr. Ray E. Trussell, and Dr. Jack Ellinson of Columbia University's School of Public Health and Administrative Medicine, Faculty of Medicine, reported on a survey of the behavior of practicing physicians making such a selection.

Of all professionals, physicians are chosen most frequently to make judgments with respect to standards for estimating the quality of medical care. This study was based on the assumption that their most critical judgments as to quality of care would be exercised in making choices for themselves and their families.

Personal interviews with 468 physicians, approximately 88 percent of a probability sample of all members in good standing of the Medical Society of New Jersey, were used as a source. Only 40 percent had a personal physician, although 9 out of 10 said everybody should have one. And only one-fifth, or 18 percent, had seen a physician in the past year for any reason.

Physicians, the authors stated, most often choose their family doctor from among full-time specialists in internal medicine who are diplomates of the American Board of Internal Medicine and fellows of the American College of Physicians. They usually choose him because of their knowledge of his technical competence; such knowledge is based on a long-standing personal and professional relationship.

The surgeon selected by physicians, according to the data, is highly specialized. He is usually a teacher

in a medical school; he is never a general practitioner. Most frequently chosen for his technical competence, he is a diplomate of an American Board and a member of the American College of Surgeons.

Nine out of ten anesthetists selected to give anesthesia for surgery to physicians or members of their families were also physicians. In obstetrics, three-fourths of the anesthetists were physicians.

Puerto Rico Promotes Rural Health Parity

Disparities in the quality and quantity of health and welfare services between urban and rural areas are being reduced by an experiment in regionalization underway in Puerto Rico, according to Dr. Reinaldo A. Ferrer, regional coordinator and director of research, Puerto Rico Department of Health.

"The project is designed to develop comprehensive and coordinated curative public health and welfare services in the Bayamón region, where 768,300 people live. It is also expected that the coordinated services will give the consumer at least a 30 percent greater return than dollars used to purchase uncoordinated services," said Ferrer.

Goals of the experiment are a two-way flow of services and technical personnel between the 15 local health centers in the region and the base regional hospital in Bayamón, continuing education for all health care professionals working in the region, and the growth of technical consciousness of health and welfare needs among the region's rural and urban consumers.

Ferrer outlined the progress that has been made toward each of these goals since the regionalization scheme was started in 1956, when the Department of Health of the Commonwealth of Puerto Rico established the Regional Office for Coordination and Research.

Although legislation passed in 1947 provided for a health center in each of Puerto Rico's 72 municipal-

ities (34 have been built), and put the hospital unit (1 bed per 1,000 inhabitants) and health and welfare units under a single roof, the three units in each municipality continued to be administered independently and lacked specific standards for organization and management.

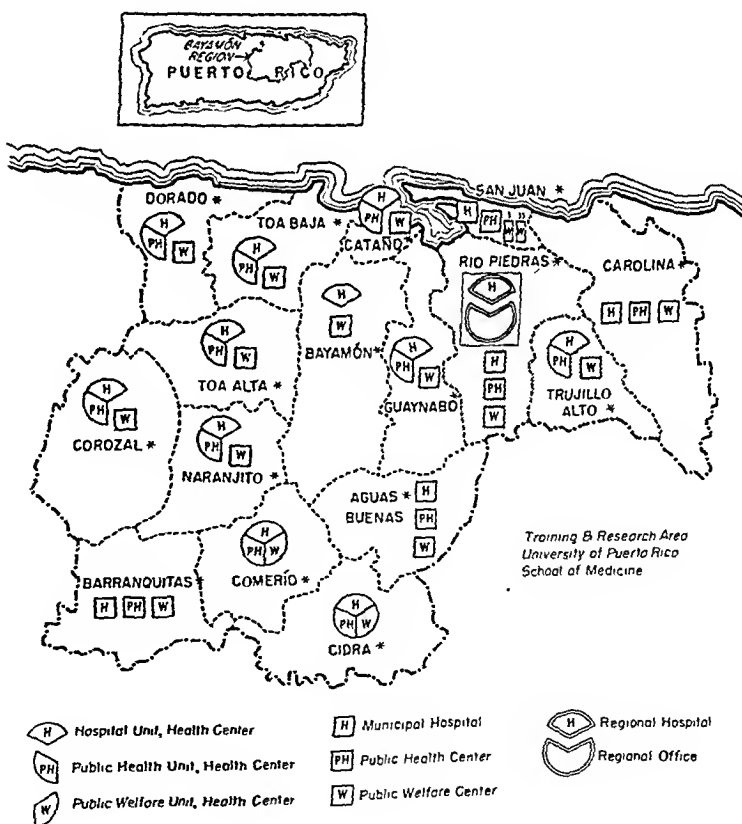

Consequently, the first task of the regional office was to compile an operating procedures manual that combined, codified, and amended the previous regulations. Standards for organization and management for each type of service within the formerly separate units also had to be prepared. Standards for 15 services have now been established, Ferrer said. "A Guide for the Opening of a New Health Center" was also found to be necessary and has been issued.

By 1958, all 15 units in the Bay-

amón region, with a proportionate number of former Commonwealth Department of Health staff, were decentralized to the regional level. Ferrer stated that the flow of services and technical personnel from the municipal centers to the regional base hospital and back to the municipality has observably reduced inequities in the health and welfare services available in rural areas of Bayamón, as compared with those available in metropolitan San Juan.

With the regionalization now in effect, chiefs of clinical services of the base hospital regularly visit the municipal centers to conduct special clinics such as pediatrics or radiology, or to perform surgical procedures. Patients now accept confidently the local center's services and no longer demand to be sent to the base hospital.

Local health centers in the Bayamón Region, Puerto Rico

Obstacles in progress toward the second goal, continuing education for professional persons, have been financial, Ferrer noted. Consultative services by the circuit riding chiefs of clinical services have not proved a satisfactory educational tool for the local centers' physicians. Therefore, systematic graduate instruction at the base hospital on Saturday mornings and longer residencies at this hospital are being tried, but both are hampered by lack of funds to pay substitutes for the absent local physicians.

Initial steps have been taken toward the third goal, to develop a technical consciousness of the needs for health and welfare services among consumers. Creation of local health councils is being stimulated by joint efforts of the local center staffs and the research staff of the regional office. In some instances, the councils have been made advisory boards with regular meetings and increasing responsibilities.

In one municipality, the augmented council prepared evaluations of community resources and facilities, communicable disease control, maternal and child health, and environmental sanitation. They used appropriate sections of the APHA "Guide to a Community Health Study" and the evaluation schedules, adapted to Puerto Rican circumstances. Their final reports and recommendations were given to the medical director of the local center. It is planned to apply the evaluation schedules to the hospital and welfare fields, and eventually use them in community education of the need for these services throughout Puerto Rico.

Consumer-Controlled Care Now Permitted In Ohio

Consumers may now organize and control medical care programs through closed panels or groups of physicians in Ohio, reported Glenn Wilson, manager of medical care research, Nationwide Insurance, Columbus.

Other departures from existing legislation contained in a new law effective October 1, 1959, were cited. Wilson mentioned that the range of health service offered by such a plan may now cover physicians' service in the home, office, hospital, and nursing home. Nonphysicians' hospital and nursing home care may be included, and dental care as well.

Wilson said the law provides that payments to professional personnel by the corporation may be on any terms mutually agreeable, and that large cash reserves are not initially required. Some States require as much as \$60,000 in cash to start such a program.

Broad power is given by the law to the superintendent of insurance to license and supervise medical service plans. One of Ohio's legislators, in discussing the enactment of the law, quoted Victor Hugo, "Nothing in the world is so powerful as an idea whose time has come."

Private Patients Get Social Services

Requests for social services for private patients come more often from the patient or a relative than from the patient's physician, according to a continuing evaluation of such requests at Beth Israel Hospital in Boston. Mrs. Beatrice Phillips, director of the social service department, and Jerry A. Solon, director of the medical care studies unit, reported on this and other early findings.

Any patient, full-paying or medically indigent, may experience social and emotional effects from illness, the authors stated, and this principle led to formal arrangements extending social services to private patients at Beth Israel upon request and for a fee. Factors which may deter private patients or their doctors from requesting or using social services, they said, are lodged in traditions of medical practice, social work, hospital organization, staff relations, and general socio-cultural practices and values.

Fully one-half of the requests originating with either a patient or a relative were concerned with home-maker arrangements and financial need. These difficulties, the authors observed, are only infrequently presented in requests by physicians. Requests by physicians were most frequently concerned with planning for discharge of the patient.

Requests were received in behalf of patients with a wide variety of diagnoses. Among chronic conditions, heart diseases and neoplasms predominated. Pregnancies accounted for another substantial group.

Variety also marked the length of stay of patients, which ranged from 3 to 77 days. All age levels were represented, including a noteworthy number of older patients.

Many questions are posed for this continuing analysis, the authors concluded, adding that the most basic are questions relating to how social service is evaluated by physicians and patients, and, conversely, how social workers look at giving social service to private patients.

Extension Service Aids Rural Health

In teaching farmers good health practices, full use of the Cooperative Extension Service of the U.S. Department of Agriculture is advocated by Dr. Donald G. Hay and Dr. Evelyn J. Niederfrank, associated with the Department.

Stating that the function of the Extension Service is basically education geared to the needs and problems of people living on farms, the authors underscored the long and successful history of this Federal educational effort. They also stressed the guiding principle of extension workers, which they said has always been "helping people to help themselves."

Reflecting what the authors described as the "growing health consciousness of the American consumer," some of the increasing demands from the farm community for health services were outlined. Home

demonstration clubs ask for lessons on home care of the sick, a clinic on well-baby care, a demonstration of farm and home safety, and lessons on what to look for in selecting health insurance coverage. The 4-11 clubs want physical examination of their members, information on surveying for farm accident rates, aid in encouraging the youth of the community to use fully a poliomyelitis vaccine clinic. A farmer asks to have his dairy herd tested for brucellosis.

Physicians and dentists in private practice and public health workers were listed by the authors as key people in the Extension Service health education program. Valid information is thus channeled to rural residents. As questions are raised, the extension staff relays the queries to specialists in the field, and arranges for dissemination of the desired information to the interested groups.

Close cooperation between health care personnel, organizations and agencies, and Extension Service staffs was urged by Hay and Niederfrank. They described the existing ties between the Service and medical schools in educational leadership in health care programs, in strengthening community health services, and in community-wide efforts toward broader use of existing resources. As an example of this cooperation, the authors mentioned a project in cardiovascular disease among farmers involving Purdue University and using the Indiana Extension Service, Indiana Heart Foundation, the Indiana University Medical School, the State Board of Health, and practicing physicians. The project is focused on the work requirements and improved work methods which may be used on a farm operated by an identified cardiac worker. Possible alternative plans for organization and operation of the farm business, graded according to the physical capacity of the farmer, are planned with and not for the impaired worker, they said.

In 1959, there were full- or part-time Extension Service specialists in charge of specific health education

programs in 18 to 20 States. In 1946, there were only three.

Fresh Concepts Outline Medical Care Patterns

The development of a conceptual framework within which various patterns of medical care can be viewed in a rational, orderly, and analytical way was reported by Jerry A. Solon, director of the medical care studies unit, Dr. Cecil G. Sheps, general director, and Dr. Sidney S. Lee, director of clinical services, Beth Israel Hospital, Boston.

In their study, supported by a Public Health Service hospital facilities research program grant, the three concentrated on the outpatient department of their hospital, but reported that the study methods are equally applicable to any medical care setting or to the population at large.

The role of the hospital outpatient department has long needed to be reappraised in the light of modern conditions, the authors said. Medical care used to consist of a simple one-to-one relationship between the patient and his doctor, but scientific specialization and growth of many varied types of care programs have made medical care much more complex today, they pointed out.

In the Beth Israel study, they sought to devise a method which would give a real sense of patterns of use and would relate the part played by the outpatient department to the total medical care of its patients.

Patients, they found, use a great many varied combinations of sources of care. Some obtain the full range of their care at Beth Israel using its outpatient clinics, the emergency unit, and occasionally ward-hospitalization. Other patients depend almost entirely upon private physicians but come to a single Beth Israel clinic for some confined purpose. Some use other hospitals and clinics. Patients continue their uses of the different sources in numerous ways.

The collection and analysis of such facts will help to reevaluate outpatient departments and assist in planning services and facilities, they said. Some key concepts of medical care patterning have emerged from the study, permitting them to obtain a sense of the person's pattern out of the maze of details. These analytical concepts enable them to:

- Delineate the patient's "current pattern of medical care," that is, the sources of care actually used during the past year and the sources he plans to use if need arises.

- Identify his "central source of care," for example, the facility or physician among these sources most important to him, or the source to which he looks for his directional signals.

- Describe the "role of his central source of care." It might be a general medical function, or a specialty service important to his well-being, perhaps a cardiologist if he is a heart patient, or a psychiatrist, or a physician-friend who may not treat the patient but will advise him.

- Finally distill from all this information what they call the person's "configuration of medical care pattern." This extracts only the essentials of his pattern of care from the whole range of his medical services.

With this framework for delineating the patients' medical care patterns, it is planned to analyze the place of the outpatient department in those patterns.

The Streetcar Named Medical Care

Medical care for members of a union can be successfully integrated into a community health program, according to Walter J. Bierwagen, president of the Amalgamated Association of Street, Electric Railway, and Motor Coach Employees of America. He cited the experience of the Transit Employees Health and Welfare Fund, established by agreement between the D.C. Transit Sys-

tem, Inc., and the National Capitol Local Division 689 of his union, in Washington, D.C.

Prepaid comprehensive medical and surgical care and hospitalization is now given to approximately 10,000 people, the employees of the transit company and their dependents, under a contract with Group Health Association, Inc., which has been operating in the Washington area since 1937. The contract became effective April 1, 1959.

The fund, originally established by agreement between labor and management in 1952, operates under the direction of a board of six trustees, three from labor and three from management. The agreement was amended in 1956 to provide for the establishment of a union health center for medical services as well as life, sickness, disability, hospitalization, and surgical insurance coverage previously supplied by the fund.

Three major possibilities were considered: to contract for expanded Blue Cross-Blue Shield coverage; to build and operate a health center for members and their families alone; or to contract with Group Health Association. The Group Health Association was selected as the most desirable, Bierwagen said. Expanded Blue Cross-Blue Shield, he stated, offered limited medical coverage and fees were not fixed firmly. The idea of a health center for members only was given up reluctantly because of delays in giving service and difficulties in doctor recruitment.

As for the Group Health Association, a cooperative society with 22,000 members, its current facilities were strained and obviously inadequate to handle an increase of 10,000, Bierwagen said. Financing was not readily available to permit expansion of these facilities. Participants in the GHA program were concerned that the quality of medical service would deteriorate because the efforts of the existing medical staff would be diluted and newer, less experienced doctors added. Medical staff

members were concerned by the possibility of meeting board requirements in the several States from which patients are drawn.

Nevertheless, medical care service has been accomplished, according to Bierwagen, with early evidence of success as a result of a completely cooperative effort. The transit employees' fund financed a labor-management health center as an adjunct to the Group Health Association in Takoma Park, Md., at a cost of approximately \$275,000. Contract negotiations, although long and complex, have been completed. Under the contract, extra fees for special services such as X-rays, basal metabolism tests, physical therapy, blood transfusions, and the like, the so-called deterrent fees, are not charged. The union's position was that these fees depart from the basic concept of prepaid medical care.

The fund pays Group Health, Bierwagen said, \$4.18 for each beneficiary, adult or child, per month. The fund also pays all the maintenance charges for the new health center and is reimbursed by Group Health at the rate of 19 cents per fund beneficiary per month, the amount budgeted by GHA for maintenance of its health facility. An active employee with family pays the fund \$8.33 per month and management matches his contribution. Lesser contributions are made for single employees and by pensioners. Although the medical services provided pensioners and their families are the same as those given active employees, the company does not match the pensioner's contribution. The contract between the fund and GHA is initially for a 2-year period, during which time title to the labor management health center is vested in the fund. Fees and benefits will be reexamined at the end of the first year.

But Bierwagen stressed that the greatest benefit is the pattern of faith now emerging among union members which permits them to use the plan with assurance that medical care is fully prepaid.

Health Insurance Plan Analyzes Complaints

Subscribers to the Health Insurance Plan of Greater New York, in response to encouragement from management, have been quick to voice dissatisfaction, ask questions, and make suggestions on medical service, reported George H. Weltner and Dr. Walter J. Lear, both associated with the plan.

Handling subscriber complaints against the plan's medical groups is the highly sensitive activity of the division of claims and subscriber service which Weltner directs. Dr. Lear, associate medical director, represents the medical department.

The plan is described by the authors as a non-profit, community-sponsored, insurance company supplying 550,000 subscribers with comprehensive physicians' services and, for many hospitalized patients, laboratory, X-ray, and auxiliary therapeutic services. About 1,000 general practitioners and specialists in 32 autonomous medical groups supply these services under contract, usually in their private offices.

For more than 10 years, complaints by subscribers directed to the central office of the plan have been counted and coded "with the obsessive zeal of a hypochondriac recording his symptoms," the authors stated. The rate of complaints is now fairly constant at 3 a year for each 1,000 subscribers. In the first 2 years, 1947 and 1948, this rate was eight and five respectively.

The most frequent complaints relate to the attitude of physicians (23 percent of the total) and to alleged superficial diagnosis and treatment (20 percent). Third in frequency (17 percent) is coded as "refused home call." Other complaints are "delayed or inconvenient appointments," "failure and delays in emergency service," "poor telephone service and other communications problems," and "wrong diagnosis or treatment."

Almost one-half of the complaining subscribers call a physician not

associated with the plan as a secondary action and most of these ask the plan to pay for the unauthorized call. In 1958, these instances, called complaint-claims, represented 43 percent of all complaints received, the authors said.

An analysis of 1958 complaints by the authors showed 58 percent against family doctors who provide 44 percent of the physician services; 11 percent against pediatricians, providing 12 percent of the services; and 31 percent against other specialists, providing 44 percent of the services.

Handling of Complaints

Complaints to the central office of the plan average seven each working day, Weltner and Lear reported. Skillful interviewing by trained subscriber service representatives frequently eliminates the need for further action. A transfer to another family physician is sometimes useful in dispelling possible antagonisms against the plan itself.

But the complaint-claims, representing about 40 percent of all complaints received, involve requests for reimbursement, the authors emphasized, and cannot be resolved by conversation. Complete information on each complaint-claim is forwarded to the administrator of the medical group concerned. Contract stipulations, according to the authors, require each medical group to supply answering reports. Both statements (the subscriber's and the group's) are then reviewed by the medical department of the plan and the representative assigned to the case. If a solution is not found at this point, the authors said further review is made by obtaining additional evidence, the testimony of impartial specialists, or by referral to a claims committee composed of the vice president of the plan, a medical department physician, the director of claims and subscriber service, the insurance underwriter, and the plan's legal consultant.

The authors reported that 30 percent of all complaint-claims are ap-

proved, based on administrative failures, the assumption that the subscriber should be given the benefit of the doubt when evidence is mixed, and, in a few cases, a clear conviction that appropriate medical care was not given.

Preventing Complaints

Thorough orientation of new subscribers lessens the higher complaint rates characteristic of the period of early adjustment of prepaid medical group practice, the authors believe. The authors described meetings held before the effective date of coverage for new subscribers and welcoming talks shortly thereafter.

Other steps in complaint prevention outlined were mailing of instructional pamphlets by the plan and a welcoming letter from the medical group which invites the new subscriber to select a family physician;

the policy of tactful interest of the subscriber service representatives in answering the questions of about 40,000 customers a year; health education meetings and bulletins; and the efforts of the individual medical groups to minimize their own complaint score.

Complaints, Weltner and Lear stated, frequently have constructive administrative results. They cited the adoption by the plan of a uniform schedule of charges for injectable drugs and biologicals after numerous subscriber complaints about variable and "excessive" charges.

The authors stated in conclusion that the voice of the patient, generally muffled in the traditional practice of medicine, is clearly heard in the plan, is recorded, played back slowly, analyzed, and often translated into practical proposals and actions.

Public Health Nursing . . .

Public Health Nurses Furnish Vital Facts

Despite difficulties in communication, public health nurses brought some 400 items of significant new information to the attention of the New York Hospital staff, according to Doris R. Schwartz, public health nursing coordinator.

A systematic study was made of a 50 percent random sample of referrals for public health nursing services initiated in the general medical clinic over a 1-year period, Schwartz reported. This study of 184 cases attempted to assess both the public health nurse's usefulness to patients as a result of the referral and the quality of communication in the referrals.

Information dealing with the patients' ability to function and not previously recorded in their charts was supplied by public health nurses, Schwartz said. Physical symptoms were often identified and mental or emotional problems revealed. Some

social problems reported by the public health nurse were referred to the social service department.

Health problems of other members of the household were brought to the hospital staff's attention, and many of these persons then came under the hospital's care. Observations on the impact of the patient's illness on other members of the family frequently were reflected in the physician's treatment plan.

Schwartz stated services requested were general nursing care; instruction in patient care; dressing changes, injections, or demonstrations of exercises; supportive health supervision; and evaluation of the suitability of a home situation.

In 53 cases, Schwartz recounted, 101 patients' problems with which the public health nurse might have been helpful were described in the hospital charts, but they were not mentioned in the original referral. Discrepancies were noted in 25 instances between orders written on the interagency referral and those in the chart.

Out of 87 specific requests from the public health nurses, the hospital answered 43. Although they invariably returned a written reply with other information on it, community agencies replied to the query in 67 of 83 cases, and the hospital remained without the information in 16 instances.

Schwartz described New York City's uniform referral system and the forms used. She suggested that staff education programs in both the hospital and community agencies be used to eliminate communication difficulties in the use of referral forms.

Research Changes Prenatal Classes

More practice in the physical act of caring for babies in prenatal classes is recommended by Ethel Donny, maternal and infant care consultant, and Mabel Reid, statistician for the Visiting Nurse Service of New York.

This change in VNS classes resulted from a study, part of a 3-year project, to improve the competence of nurses in work with young parents. Questions designed to discover what the prospective parents were like, how much they learned in VNS classes, and how they adjusted to their new role as parents revealed that attendance was lightest among the least privileged.

Classes now are offered only in middle-class neighborhoods where attendance remains consistently high. They found that the women who attend classes are relatively well educated, have had little or no contact with babies, and are in close contact with their physicians.

As a result the classes provide additional opportunities for practicing baby care to supplement the individual baby-bathing practice session arranged for each mother before or after class. Parents are encouraged to diaper dolls rather than watch the nurse demonstrate different types of diapers. The feeding bottle is passed around to parents to practice its use.

The authors declared they were surprised to learn that the terminal heating method of sterilization, the only method taught in the class, was used by only half of the women who prepared formula. Now they discuss and demonstrate the aseptic method as well, stressing cleanliness but de-emphasizing sterility.

Half the women who attended classes had difficulty adjusting to their new role during their first week at home with the baby, and described it as an unhappy experience. These mothers were particularly upset by the baby's crying. The authors believe that a mother who becomes familiar with a crying baby in the hospital, while she is in a safe situation, may not be so disturbed when her baby cries at home.

Instead of suggesting that parents hire a housekeeper or infant attendant, VNS instructors explain the actual tasks of a new mother and encourage expectant parents to make their own plans for coping with them.

According to Donny and Reid, women who come to classes and their babies have private medical care. When mothers were interviewed between 4 and 8 weeks after delivery, the infants had already been seen by the physician an average of two times since leaving the hospital. An average of 3.4 calls had been made to the doctor for specific advice, generally concerning feeding. In deference to doctors' differences as to when solid foods are to be introduced, the authors said, they concentrate on how to do it.

Group instruction as they have developed it, Donny and Reid stated, does not attract parents from the lower socioeconomic levels or new immigrants, the families with the highest perinatal mortality. In areas where attendance was consistently low, prenatal classes have been discontinued in favor of more antepartum home nursing visits. All nursing time available for maternity work in these sections of the city is spent in home visits to encourage women to register for early prenatal care and keep their clinic appointments

and to teach good nutrition and hygiene, with teaching adjusted to each mother's individual needs.

With respect to the need, they concluded that group instruction as an alternative to individual teaching, is a dubious economy in prenatal education.

Home Nursing Lightens Chronic Illnesses

Home nursing and other health services organized for patients discharged from North Carolina Memorial Hospital in 1953 have broadened into a demonstration of unusual opportunities for limiting disability and chronic disease. This conclusion was reported by Dr. William L. Fleming, Shirley Callahan, and Dr. S. L. Warren, respectively professor, instructor, and assistant professor in the department of preventive medicine at the University of North Carolina at Chapel Hill.

Beginning with a teaching grant from the Commonwealth Fund, the home health service arranged for medical students in their fourth year to provide medical care to selected homebound patients living within 10 miles of the hospital, and bedside nursing services were arranged through the district health department.

As it became known that such home services were available, the supervising nurse of the service began to receive requests for assistance to antepartum cases. At the same time, demands increased for aid to nonmaternity cases, some of them outpatients and others on discharge from the hospital.

In light of this demand, in 1955, health officers for the State's 100 counties were asked if they could provide instructions and bedside nursing services in the homes of discharged patients, and health officers for departments covering 95 counties responded. Nearly all offered counseling services, but their estimates of availability of nursing services varied considerably.

Much of the variation resulted from their different anticipations of

the special services that might be required. In practical experience, it was found that reasonable requests for bedside nursing care have been seldom refused by a local health department.

Referrals are initiated by any professional person in the hospital, but are completed by the attending physician and coordinated by the supervising nurse.

Although most of the new referrals, in the range of 2 or 3 a day, have been maternity cases, the proportion of patients with chronic illnesses on the referral list is rising. Of 445 nonmaternity patients referred in 1958, 143 had CVR conditions, 61 diabetes, 31 paraplegia, 30 neurogenic and mental illnesses, and 28 cancer.

The percentage of referrals for home evaluation has also been increasing. For example, home evaluation is used by the pediatric service in behalf of the nephrotic or rheumatic child.

It is believed that home evaluation can reduce failures to keep clinic appointments, disease complications, and readmissions. It also helps in planning a regimen within the patient's capacity.

The opportunity for home service at the same time makes it practical to expedite the discharge of patients with amputations, surface ulcers, colostomies, tracheostomies, strokes, and arthritis.

The authors of the report recommended that health departments not only place more emphasis on providing home nursing services but that they also should join with the community hospital in providing certain laboratory services, such as culturing streptococci, so as to assist in the correct use of antibiotics.

Nursing Budget Uses Activity Time Data

Work measurement and performance budgeting in public health nursing are being used by the bureau of public health nursing of the Los Angeles County Health Department to

support budget requests for nursing personnel, reported its director, Olive M. Klump. These techniques have enabled the bureau to compute the anticipated volume of work to be performed at the standard which has been determined by the professional staff.

In the budget process, Klump said, health department nursing services are listed in major categories and totaled. Nursing time of all district nurses reported for each category for the period selected for study is tabulated. The total number of units in each category, divided into time consumed, gives a figure for the average time per unit.

Indirect time, Klump explained, is analyzed and tabulated into arbitrarily defined categories which include inservice training, supervision, public relations, health education, cleaning the nurse's bag, attending professional meetings, and preparing field, time, and mileage reports. Indirect time reported for all district nurses for the period studied is totaled, and a percentage ratio of the indirect to the direct time computed.

In projecting budgeted time, indirect time is added to direct time, after determining the proportion of indirect time to direct time for each district.

Data obtained in this manner have been used to indicate the number of nurses needed in each existing district, for new districts, and for new or changed programs, Klump stated. The data also bring out variations among districts. As a result, certain nursing activities are being reexamined.

Klump pointed out that quantitative appraisal of nursing services is not sufficient in itself. Services and the time allowed vary with need and conditions, and with standards of care. When only top priority home visits are made and when the time per visit is the only consideration, she said, the volume and quality of service will be inadequate.

Although the budget process is quantitative, not qualitative, Klump affirmed that it does encourage the examination of performance standards which can be used in conjunction with quantitative data.

The procedure was adapted from the field of industrial management, but it is patterned after another study in public administration in Los Angeles County, Klump declared. The procedure is practical, acceptable to management, and facilitates planning for nursing services, she concluded.

Maternal and Child Health . . .

Early and Cluster Testing Urged for Phenylketonuria

To wait for initial retardation symptoms suggesting phenylketonuria in infants is to wait too long; treatment must begin in early infancy to avert irreversible brain damage, asserted Dr. Willard R. Centerwall, Dr. Robert F. Chinnoek, and Albert Pusavat, of the department of pediatrics in the School of Medicine of the College of Medical Evangelists, Los Angeles, Calif.

They advised screening all well babies, as in California, where health

departments participating in well-child conference testing are checking the majority of infants seen by health departments in that State.

Phenylketonuria (PKU), also known as phenylpyruvic oligophrenia, is a recessively inherited disorder in the metabolism of the amino acid, phenylalanine. It is characterized by high phenylalanine blood levels and the presence of phenylpyruvic acid (a phenylketone) and other metabolites in the urine. Infants with PKU are normal at birth, but within a few months they begin to show signs of mental

retardation; and by 2 or 3 years of age more than 90 percent of these children have progressed to the imbecile-idiot level of mental deficiency. Between 0.5 and 1 percent of the institutionalized mental defectives in this country have PKU. Interpolating from this incidence in the defective population, it is estimated that PKU probably occurs once in about 20 thousand live births. It is possible that it is even more common than this. About 200 PKU infants are born in the United States each year.

The monetary savings to the taxpayers when any such child is spared a lifetime admission to a State institution for the mentally retarded is about \$100,000 for that one child. If each such infant were to be discovered early and thus prevented from becoming mentally retarded and institutionalized, the theoretical savings to the Nation's taxpayers for only 1 year's successful detection would be in the neighborhood of \$20 million spread over the lifetime of these children.

The bulk of the report discussed technical aspects of screening and testing. On detecting phenylketonuria, they suggested, the families and physicians should be alerted to assure early diagnosis of siblings and cousins. Screening mentally deficient populations together with family orientation and sibling testing found four new cases in a recent 3-month period in southern California.

A Central Registry

A central registry for phenylketonuria will encourage recognition of every case of this disease in a given area, in the opinion of Dr. Richard J. Allen, assistant professor of pediatrics, University of Michigan Medical School, Ann Arbor, Mich. He urged a cross-checking system between the family physician, the pediatric diagnostic clinic, and the State mental institutions so that all infant examinations and the evaluation of all neurologically defective children are accompanied by routine urine tests to identify phenylketonuria.

Fifteen patients were detected this way in the past 3 years in the university's pediatric department.

Efforts to detect this disease must be simple, easily interpretable, and not too costly because present statistics indicate phenylketonuria is a rare disease. Testing only infants in well-baby clinics may require many years to identify even a single case, depending on the population of that clinic. Identifying older patients has been a worthwhile study, Allen said, since the recent survey of State institutions in Michigan has detected 34 cases. Family surveys may then identify infants with the disease at an age when treatment is most effective.

In discussing testing techniques, Allen remarked that there are several sources of error, particularly when using the ferric chloride method. False negatives may result from insufficient amounts of ferric chloride added to the urine while false positives may be due to color changes associated with various drug ingestions. Some errors may be avoided by diluting the urine specimen with a large volume of distilled water before adding ferric chloride. In general, the diagnosis is easy, particularly with the commercially prepared paper strips but also with chemicals (ferric chloride solution) usually found in the physician's office.

Cystic Fibrosis Strains Family Resources

The increasing numbers of children and young adults with cystic fibrosis present difficulties new not only to physicians but to their families and communities, stated Dr. Dorothy H. Andersen, department of pediatrics, Columbia University College of Physicians and Surgeons, New York City.

She explained that earlier diagnosis and informed therapy have meant prolonged life for patients with this relatively common congenital disease. Twenty years ago, most

died in infancy with malnutrition and bronchopneumonia. Andersen called the disease a public health concern and explained why the patients and their families need medical, financial, educative, and supportive help.

In cystic fibrosis of the pancreas or mucoviscidosis, many or all of the exocrine glands function abnormally. The glands chiefly affected (each in somewhat different ways) are the mucous glands of the bronchi and nasal passages, the sweat glands, and the digestive glands. The most common clinical results are chronic bronchitis, malnutrition or poor weight gain, steatorrhea with loss of fat-soluble vitamins, and susceptibility to heat prostration. Respiratory infection produces the most distressing symptoms and is the usual cause of death.

A physician or a clinic familiar with the disease, able to instruct the child's mother and provide continued support, must supervise the immediate care of the patient. The child needs a planned diet, daily vitamin supplements, salt tablets, and, usually, antibiotics of some sort.

The mother faces many questions. Are associations with other children in school and at play worth the risk of exposure to infection or is isolation of the child a greater risk? How much exercise should the child have? How should she explain the child's condition to neighbors and relatives?

The patient, as he reaches adolescence, wonders how long a life he should plan for. Should he marry? What kind of work can he do?

The financial cost of the disease, aside from hospitalization expenses, has been estimated at \$1,000 to \$1,500 a year for drugs, X-rays, trips to the clinic, and high protein foods. Families with moderate incomes sometimes deprive other members to feed the patient, and some sell their homes to pay the bills.

The genetic implications of the disease are troubling. Parents face the question of having additional children, and the present status of knowledge of the disease offers no

definite answers. The genetic pattern of cystic fibrosis is not clear, and the basic metabolic defect which is inherited is, as yet, unknown. Whether dominant or recessive, the trait is irregular in penetrance and expression. It occurs among siblings with the frequency of a recessive trait. Sex distribution is equal. Occurrence is not related to age of parents, sibling order, or economic status. It has been calculated that if cystic fibrosis is recessive, 1 in 20 of our population carries the gene, which seems improbable, according to Andersen.

Frequency of occurrence has been estimated as of the order of 1:1,000 live births. The number of living patients or the number of deaths annually from cystic fibrosis is not known. Babies Hospital in New York City sees 50-60 new cases a year, is following 250, and Boston Children's Hospital sees about 100 new cases a year. There were an estimated 2,500 hospital discharges (1 in 7 discharged by death) with this diagnosis in 1957.

For all these reasons, families feel isolated by what seems a unique dilemma. They often resent their physicians' lack of knowledge which may have delayed diagnosis and are frustrated in attempts to obtain assistance from public agencies.

Andersen suggested, in addition to more research, wider dissemination of what is known among physicians, schools, and public health agencies. Pediatricians and recent medical school graduates are best informed, but many physicians know little more than the name of the disease, she said. With informed public health centers, school nurses, and social service agencies, families with affected children might be better provided with counsel and support. Counseling services for the increasing number of adolescents and young adults would be invaluable, she said.

Some States have eased the financial burden of the disease; for example, in Connecticut the cost of drugs and vitamins is borne by the State. In many States, the laws ex-

clude patients with the disease from receiving State aid.

Additional knowledge is being sought. The Children's Bureau, Department of Health, Education, and Welfare, is studying the occurrence of the disease. The National Institutes of Health has recently established a research group. The National Cystic Fibrosis Research Foundation, organized by parents, is raising funds for research and education. Clinics in a number of children's hospitals are absorbed in the medical care of patients and in basic research.

Lower Chloramphenicol Dose for Infants

Factors in the rising neonatal mortality rate in Baltimore in 1958 included lack of prenatal care, the possible existence of a pathological agent in hospital or community causing febrile illness in mothers, and, possibly, excess dosage of chloramphenicol in the newborn, according to a recent epidemiological study reported upon by Dr. M. Kathleen Carney, instructor in public health administration, Johns Hopkins University School of Hygiene and Public Health.

Currently, for the first time since national mortality statistics have been available, there is a nationwide rise in neonatal mortality rates. The rise in Baltimore, most marked among Negro and premature infants, began in 1957, with the rate going from 22 per 1,000 live births in the preceding year to 26 per 1,000, a difference accounting for an excess of 118 neonatal deaths in 1957. The elevation persisted in 1958 and through the first 6 months of 1959.

The Baltimore City Health Department reported that the increased mortality was limited to the neonatal period. The death rate per 1,000 live births for infants aged 28 days through 11 months remained almost stationary, and there was also no parallel rise in fetal deaths. The increase in actual number of deaths was most marked at 24 hours

through 6 days of age. There was no rise in natal day mortality. Ninety-four percent of the neonatal deaths occurred prior to the infant's initial discharge from hospital of birth. The rise was not uniformly observed in all hospitals of the city. Primarily, according to the department, it was a problem of the Negro infant.

The study was made in 1958 at two Baltimore hospitals with 50 percent of the Negro births in the city. Hospital A is the municipal hospital, in which nearly 40 percent of all Baltimore Negro babies are born. Overcrowding and understaffing exist on both obstetrical and nursery services, Carney said. Hospital B admits both private patients of staff physicians and ward patients who have been followed regularly in the hospital obstetrical clinic. It also serves as a referral agency and receives a considerable proportion of patients with complications and greater prospect of poor fetal outcome. Overcrowding is not so great here, according to Carney.

In both hospitals, obstetrical records of all mothers experiencing live births in the first 4 months of 1958 were analyzed and compared with control periods in 1956, the most recent year of significantly lower neonatal mortality. All recorded neonatal deaths during the first 9 months of 1958 were studied in detail including evaluation of all available necropsy data.

At hospital A, an increase was noted in numbers of patients failing to obtain the prenatal care offered by the city health department.

Here also was noted an increase in incidence of mothers' postpartum puerperal morbidity which may have affected the health of their infants. Data from the study concerning the incidence of fever after delivery led to the hypothesis, Carney said, that during 1958 there was possibly present in the obstetric department or community an agent (perhaps bacterial, viral, or other) which produced a febrile reaction in certain mothers in the postpartum period and may have been responsible for

the neonatal death of some of their infants. Such an agent was not detectable by routine laboratory studies performed on febrile mothers.

A change in age distribution of neonatal deaths at hospital A with an increase in proportion of infants becoming ill and dying after the first 48 hours of life led to investigations of antibiotic dosage of all infants surviving for 24 hours but dying within the neonatal period. Only two statistically significant differences in antibiotic therapy were found between 1958 and the 1956 control period, Carney reported. These involved decrease in use of streptomycin in prematures in 1958 and an increase in use of chloramphenicol in doses in excess of 50 mgm./kgm./24 hours in prematures in 1958.

The chloramphenicol dosage was of particular interest, Carney said, in light of recent reports suggesting that doses in excess of 50 mgm./kgm./24 hours might be toxic and at times fatal to small infants because of poor ability to convert and excrete it. Evidence was insufficient to be conclusive on this point, but, Carney said, "there is reason to consider this factor a lead." Since the report, the standard therapeutic dose has been altered to 20 mgm./kgm./24 hours, and coincidentally there has been a significant decrease in the mortality rates of premature infants weighing over 1,500 gm. at birth.

At hospital B, nearly 70 percent of the rise of neonatal mortality could be explained by an increase in number of immature (less than 1,000 gm.) births and deaths. This is an apparent consequence of a particular interest in the treatment of habitual aborters at this institution, Carney explained. There was no evidence to suggest any significant increase in deaths due to infection or other illness acquired in the nursery at hospital B.

Economic Status

Colors Birth Data

Changes in characteristics of the population of the District of Co-

lumbia, with relative gains in the low income group, clearly reveal the impact of economics on birth data, according to Dr. Ella Oppenheimer, chief of the bureau of maternal and child health, D.C. Department of Public Health.

Premature and illegitimate births and neonatal mortality have increased and prenatal care has decreased in recent years, Oppenheimer reported.

The population of the Washington metropolitan area which spills over into Maryland and Virginia has grown in both white and nonwhite components in recent years, and the relative proportions have remained relatively unchanged. However, in the District of Columbia, itself, the population pattern has altered.

The white population, which in 1950 represented 64 percent of the total, now amounts to only 47 percent of the city's total. In the same period, the nonwhite population has increased from 36 percent of the total population to 53 percent.

An important factor in this change is income. Of the nonwhite residents, 66.3 percent had incomes under \$5,000 a year, compared with 30.8 percent of the white residents. Of the nonwhite citizens, 31 percent had incomes under \$3,000 a year, compared with 11.6 of the white.

Estimates in 1957 showed 53 percent of the nonwhite and 17 percent of the white citizens unable to pay for hospital care. Even more significant of the economic status of the present childbearing population in the District, Oppenheimer pointed out, are the relative proportions of births under private medical care and hospital staff cases. Approximately 60 percent of all births to resident mothers, white and Negro, are staff cases. For the white births, between 18 and 20 percent were staff cases; for the nonwhite, more than 75 percent.

This lack of funds to pay for private physician care or hospitalization is reflected in lack of prenatal care, which in turn contributes to increases in premature births and neonatal mortality. In 1958, with

12.5 percent of the District of Columbia births premature, the percentage for those with prenatal care was 10.4 percent; for those without prenatal care, 22.7 percent. Neonatal mortality among the nonwhite portion of the population is high and increasing, Oppenheimer said.

Program action has not kept pace with the need for public services brought about by this change, Oppenheimer reported. Although the situation is now well recognized and steps are being taken to remedy it, she said, "the loss which has occurred is irretrievable."

Social Distress Invites Premies

Stress occasioned by depressed socioeconomic conditions surrounding the mother may contribute to premature delivery and stillbirth, according to findings reported by Helen Wortis, instructor in psychiatry, and Dr. Alfred M. Freedman, associate professor of psychiatry, State University of New York, downstate medical center.

Wortis and Freedman drew their information from the histories of mothers of 267 premature infants (2,100 grams or less) cared for in the premature nursery at the Kings County Hospital in 10 months of 1956-57. The area served by the hospital is highly congested and is known to have a high incidence of premature births. Its population includes a large proportion of Negroes and Puerto Ricans. Of the mothers studied, 80 percent were Negro, 11 percent Puerto Rican (both white and colored but mainly white), and 9 percent white. The hospital serves only the medically indigent.

As anticipated, the mothers studied came from families of low income, 71 percent under \$4,000 a year, 18 percent under \$2,000. Twenty-three percent of the mothers had received no prenatal care; an additional 34 percent had not started such care until the third trimester of pregnancy. Although 61 percent lived in their own apartments, many

had to share kitchen or bath facilities. Thirty-five percent lived in homes where the number of persons per room was more than 1.5; 3 percent had a crowding index of 3.51-4.50.

The predominant symptom of social disorganization in this premie population was the breakdown of the family, Wortis and Freedman said. Thirty-one percent of the group studied were unmarried. Of those who were married, many were separated from their husbands. Family breakdown, moreover, was a continuing pattern, not beginning or ending with this generation. Many of the mothers had themselves spent their childhood in broken homes, and 10 of the premature infants (1 in 24 of those surviving the nursery) were refused by their mothers and discharged from the hospital to a public agency.

"It is difficult to adequately describe the quality of life histories which we elicited," Wortis and Freedman said, "For most of these women the birth of a premature child was only one traumatic event in a life experience which contained many. Their histories were so different from what we think of as an average experience in our culture that the nearest equivalents we could think of were the vagrant characters flitting through Gorky's Lower Depths or Caldwell's Tobacco Road."

Term Controls

A control group, drawn from the same area and hospital, was made up of women who delivered at term during the same period and included representatives of the three ethnic groups considered. They could be presumed to come from the same social class as mothers of the prematures, Wortis and Freedman stated. Although the sample was small, no important differences were noted in place of birth, education, source of income, work status at conception, or length of time in New York.

In interviews with them, Wortis and Freedman gained the general clinical impression that these women

were less tense and upset. Two important statistical differences were noted. The mothers of term infants were older (only 10 percent under 20 years of age compared with 26.5 percent under 20 among the premie mothers), and the term mothers were more likely to have had prenatal care and to have started it earlier. Twenty-three percent of the premie mothers had had no prior medical care, while only 4 percent of the term mothers had none.

Conclusions

Among the variety of causes found for premature delivery, maternal environment and social status have an important bearing, Wortis and Freedman said. "Poverty means early pregnancy, poor medical care, and broken families. In terms of individual experiences, it means an accumulation of stressful situations which must be alleviated by broad programs of social care aimed at elevating living standards and eliminating the social situations which we have observed. Better nutrition and housing, adequate financial resources, equal opportunities for education, and maintenance of family life and structure are essentials for attacking problems of premature delivery as associated with low socioeconomic status."

Pregnancy Losses Lower In Health Insurance Plan

Prematurity and perinatal mortality rates were significantly lower among members of a prepaid group practice comprehensive medical care plan than among the total New York City population delivered by private physicians.

Sam Shapiro and Dr. Paul M. Deason of the Health Insurance Plan of Greater New York and Dr. Harold Jacobziner and Louis Weiner of the New York City Health Department reexamined a finding reported 2 years ago (pregnancy loss in HIP was lower than that in the general population of New York City) by

limiting their sample to patients delivered by private physicians. They also investigated the possibility that socioeconomic differentials and the greater availability of diplomates in obstetrics and gynecology in HIP account for the more favorable experiences in the medical care plan.

Comparison for 3 years (1955-57) showed that prematurity rates per 100 live births (adjusted for differences in age of mother and ethnic composition of the groups) are 5.7 for HIP and 6.2 for patients of private physicians. Adjusted perinatal mortality rates per 1,000 single live births and fetal deaths (20 weeks or more of gestation) were 23.1 for HIP and 27.9 for patients of private physicians.

According to the authors, data for 1955 showed that HIP did not have a more favorable distribution of occupations (of father) than the patients of private physicians and that, within virtually all broad occupation classes, HIP had lower prematurity and perinatal mortality rates.

The authors regarded as suggestive, but not conclusive, these two findings: to the extent that occupation of father reflects socioeconomic status, HIP's lower rates are not a consequence of this factor; perinatal mortality rates for diplomates in obstetrics and gynecology were lower than for other private physicians in the city but higher than for HIP. However, there is a possibility that diplomates in the city get more poor-risk cases than other private physicians. If so, this would affect the comparison with HIP.

Aside from the comparisons between HIP members and the patients of private physicians, the authors listed these significant findings for the entire city. Even in the highest occupation classes, only a small proportion of nonwhite and Puerto Rican women used private physicians. The stage of pregnancy when prenatal care began was affected by socioeconomic status, where the mother gets care, and ethnic group. In both white and nonwhite groups, there were major differences in pre-

maternity and perinatal mortality rates between general service (ward) cases and cases of private physicians.

The authors suggest taking a fresh look at differentials in pregnancy loss among other subgroups in New York City. They propose investigations to clarify cultural traits and attitudes of population subgroups and the influence of these attitudes on health practices prior to and during pregnancy. Also, much more needs to be known about the management of obstetrical care among patients of private physicians and about the general service cases, they said.

Mental Retardation Needs Diagnosed

Diagnostic data on 431 "mentally retarded" children, studied at three pilot State diagnostic and parent counseling clinics and three cooperating clinics for 8 months of 1959, were presented by Bernard Ferber, associate biostatistician, and Dr. I. Jay Brightman, executive director, New York State Interdepartmental Health Resources Board.

The board was established to supply a multidiscipline approach to all health problems. Teamwork by professional disciplines is a mandate, the authors indicated, in determining needs and giving indicated services to a mentally limited child.

Tabulation of information on the 431 children revealed:

- Of the children seen, 57 percent were under 6 years of age.
- Twice as many boys were referred as girls.
- Referral sources were 32 percent, hospital or clinic; 23 percent, private physician; 15 percent, family, relative, or friend.
- No previous specialized service had been given 38 percent of the children, and relatively few had received an adequate diagnostic study.
- Ninety-three percent were accepted and completed the diagnostic workup.

• Mental retardation was diagnosed in 74 percent of the children, 13 percent were questionable, and 14 percent were classified as not mentally retarded.

• Approximately 85 percent of the services recommended were considered available, 15 percent were not.

• Of the children studied, 212 were of school age; 58 percent of

these were attending school, 42 percent were not.

• Prognosis, based on ability to function ultimately as an adult, was nil or poor for 24 percent, guarded for 52 percent, and good for 25 percent.

• Most frequent services recommended were schooling and training, and speech and hearing evaluation, including therapy and casework, and counseling.

Dental Care . . .

Diet Studies Explain How To Save Teeth

Two studies of diet, reported respectively by Dr. Robert L. Weiss, Public Health Service, and Margaret A. Dunham, director of nutrition, Indiana State Board of Health, both found a high association between carbohydrates and tooth decay, but with different emphases.

The study reported by Dunham found that the decay rate increased in relation to the rise in the level of carbohydrates in the diet. The Weiss study found that frequent eating of snacks between meals, preponderantly chewing gum, candy, soft drinks, pastries, and ice cream, is associated with a high def (decayed, indicated for extraction, or filled) index.

Weiss noted that modern research in dental health is guided by two hypotheses as to the relation between carbohydrates and caries. One is that the frequency of eating carbohydrates, especially foods containing sugar, influences the development of caries. Second, the consistency or chewiness of the food is an important factor.

The study under discussion examined 783 children in western Tennessee, 5 to 7 years old. Parents were asked which items of food, on a prepared list, had been eaten

by the children on the previous day, and how often they had been eaten.

Specifically, Weiss found that there was a direct and consistent relationship between the frequency of eating between meals and caries experience. As the frequency of eating between meals increased, a corresponding increase was noted in the number of def teeth per child.

Utilization of findings of this kind in dental health educational programs, Weiss said, will enhance the effectiveness of these programs. Knowledge relating to between-meal eating can be easily understood by the public and can be easily applied throughout the course of everyday living.

The Indiana study, which surveyed 222 boys and girls aged 11 to 14 in 1947, was based on a 7-day food-habit study. It also asked about the frequency of eating carbohydrate foods, as well as the total milk intake daily.

This survey found the average daily intake of carbohydrates was 34.15 teaspoons per day. The frequency was 4.9 times per day, including meals, or 1.9 between meals. The average DMI (decayed, missing, filled) rate was 3.9. Half of the students had some degree of inflammation of the gums. Average milk intake was 2.67 glasses per day.

In connection with the Indiana

study, educational efforts were aimed at recommending a good diet, with a restriction on carbohydrates, and correct cleaning of the teeth after eating.

The dental health education program in Indiana, as described by Dunham, includes a cooperative activity conducted by the State Board of Health, the Purdue University Agricultural Extension Service, and the State Dental Association.

She also described State activities for developing nutritional aspects of dental health education among professional personnel.

Inservice training programs for teachers, usually consisting of an hour's meeting at a central school in the community, begin with a platter of snacks, designed to demonstrate the attractions of food low in refined carbohydrates. Platters include apple quarters, orange sections, pineapple slices, cauliflower bits, celery stuffed with cheese and peanut butter, carrot sticks, green pepper rings, sliced raw turnips, and nuts. Teachers are also offered milk, unsweetened fruit punch, and coffee.

Food surveys are recommended to the teachers, as a means of combining research and education.

Teachers are advised to speak in the primary grades of groups of foods, rather than of specific nutrients, and to emphasize the value of citrus fruits, green leafy and yellow vegetables, and milk. Rather than advocate special courses in nutrition, it is recommended that the subject be introduced naturally in connection with the established curriculum.

Two pamphlets used widely in the program include "Nutrition and Dental Health," published by the American Dental Association, and "Smackin' Good Snacks," published by the Indiana Board of Health.

Dental Care Approaches Needs of Aged and Ill

Several papers on the subject of dental public health explored the needs of the aged, chronically ill, and the handicapped, with respect to

patterns of care, techniques, facilities, and personnel.

Dovetailed Services Urged

A plea for coordinating all dental care activities within the community for the disabled and chronically ill was offered by Dr. Marvin P. Sheldon, dental consultant of the Chronic Disease Program, Public Health Service. No single community has done this, to his knowledge.

Sheldon enumerated major conditions disabling about 5½ million noninstitutionalized persons in the country. Among typical community dental resources for them, he considers the dental society pivotal.

Hospital dental departments need expansion, he said. General hospitals give a sixth of their beds to long-term patients, but only 28 percent of all hospitals have dental services, sometimes only for exodontia or emergencies. Neither does the resident of the average nursing home of 20 beds have the dental service he badly needs.

Organized home care programs, now only 53, use dental clinics, sometimes in a hospital during special hours, or go to the patient with portable equipment. One city health department lends such equipment on appointment to members of a cooperating dental society. A portable unit including motor and arm, storage space and drawers, and working on ordinary house current is undergoing field trial, Sheldon reported.

Community dental activities should work as part of existing evaluation and diagnostic clinics, he said. These clinics give disability profiles and prognosis for medical rehabilitation and thus give a firmer base than dental treatability evaluation alone. Sources of financial aid for homebound patient projects include, according to Sheldon, existing Federal aid agreements, private philanthropy, State health and welfare funds, and nonprofit insurance companies.

The Kansas City Project

Community and professional leaders, conditioned to the impor-

ance of dental health for children, must be oriented to the value and importance of dental health to the aged and chronically ill, asserted Lewis W. Andrews, director of the Kansas City Dental Research Project, Public Health Service.

The project, established in 1957, is carried out in cooperation with Community Studies, Inc., and the University of Kansas City School of Dentistry. Health education media have assisted in acquainting the community with the purposes of the project, that is, to determine the nature and extent of dental service needs of the aged and chronically ill and problems involved in the treatment.

As a part of the project, a training program for senior dental and dental hygiene students has been established.

Personal contact with administrators of the original sample of 44 nursing homes (of a known 84) was responsible, in Andrews' opinion, for the good response. Prior recording by dental assistants of patients' medical and vital data saved time.

Three out of ten refused treatment: "My teeth will hold out as long as I will." "I don't want to be bothered." "You tend to your business and I'll take care of mine." Appointment cards for the 78 percent transported to the clinic resulted in few broken appointments. About 15 percent had home treatment and 7 percent came by ambulance. When dental care is completed, reexamination follows in 6 months. Also, new nursing home residents are added continually.

Out of a roster of 3,000 homebound chronically ill, compiled from records of voluntary health agencies, hospitals, welfare agencies, and religious organizations, 60 percent of the 964 selected were available for examination. Preplanning and organization, as in the nursing home phase, brought few refusals. About 9 percent were treated at home, 5 percent came by ambulance, and a few by their own means.

A total of 2,210 patients with an average age of 70 have received

dental examinations. Six out of ten patients examined needed and could be expected to benefit from treatment.

Cost and lack of transportation appear to be the major blocks to utilization of dental services. The dental profession is interested and willing to cooperate in dental programs for these patients.

Whether or not dentures are essential for maintaining nutrition of the edentulous chronically ill or aged patient was among criteria for measuring dental treatability of such patients outlined by Dr. Stanley Lotzkar, clinical director of the Kansas City dental project.

Other considerations are:

- The extent and duration of previous periodontal disease.
- Duration of edentulousness, patient's adaptation to it, and his probable tolerance for dentures.
- The presence of systemic disorders affecting healing, such as syphilis, diabetes, or arthritis.
- If partially edentulous, whether or not partial dentures will mean eventual loss of abutment teeth.
- Esthetic contribution to the patient's morale.

Lack of teeth sometimes seems to hasten aging, Lotzkar remarked. A patient's positive attitude can overcome numerous hurdles; but when negative, ideal conditions may not help. In treating those maladjusted to their physical disability, he advised patience, sympathy, and morale-lifting attention.

Lotzkar believes in keeping many serviceable teeth, if they are without pathology, even though the teeth may be mobile. The goal should be comfort, cleanliness, and the patient's well-being. Because of the effects of drugs such as anticoagulants, corticosteroids, and insulin, he urged consultation with physicians before surgical procedures for the chronically ill.

Since neglect of oral hygiene is widespread, dental hygienists are vital auxiliaries to dental care, including frequent prophylaxis, dental health education, and sereneing.

Outlining essential features for

equipment used in home dental care, Lotzkar included use of lightweight metals, better operating lights and positioning devices, a combined aspirator and air compressor, and separate units for surgical, prosthetic, operative, or periodontal treatment, in a single manageable case.

The Philadelphia Handicapped

Workshops for nurses, physicians, and parents stressing the need for dental care of the handicapped in Philadelphia were cited by Dr. Manuel M. Album, lecturer in the University of Pennsylvania School of Dentistry, as a technique to combat the ignorance and apathy he feels is slowing the spread of such care.

Dentists were portrayed as both community initiators of such activities and educators of hospital, parent, or other groups interested in the handicapped. He believes that par-

ent groups, welcoming dental projects as a step toward total care, will help finance dental clinics.

Album made the point that when dental treatment of a handicapped patient is required under a general anesthetic, it be given only in the hospital and that hospital officials and attending dentist should know each other's plans and requirements. Definite hospital time must be allocated and respected, he said, adding that the dentist should know operating room techniques and procedures. All such costs in Philadelphia are covered on a semiprivate basis by a hospitalization plan, he reported, and for the indigent handicapped, by the Pennsylvania Department of Health, in hospitals it certifies. The department also underwrote tuition in courses on dentistry for the handicapped given in the University of Pennsylvania School of Dentistry.

Epidemiology . . .

Poison Study Indicts Careless Storage

The nature of accidents involving poisons or potential poisons among children under 5 years, tends to vary with age, it appears from an analysis prepared by Dr. Howard M. Cann, Albert P. Iskrant, and Dorothy S. Neyman, all with the Accident Prevention Program of the Public Health Service. But a high proportion of the incidents occurred with poisons outside their usual containers or places of storage.

Using information obtained since 1957 from the National Clearinghouse for Poison Control Centers, the authors reviewed more than 15,000 reports, of which 14,069 were classified as poisoning accidents. Of these, 90 percent concerned children under 5. About 60 percent of the 14,000 accidents concerned children between the ages of 1 and 3. The

highest incidence of poisonings was at age 18 to 24 months.

The younger the child, the more frequently the poison was obtained outside of its original container: for those under 1 year, about half of the poisons came from the original box or bottle. About a fourth of the 4-year-olds found the poisons outside their pristine packages.

The kitchen was the most frequent site of the incidents, accounting for 40 percent. More often than not, the chemicals were outside the customary storage place, and outside the primary package in one-fourth of the kitchen incidents. The bedroom was the next most common site.

Poisons were found most frequently on top of tables or chests, next most frequently in cabinets.

In 84 percent of the incidents, the children were presumably under parental supervision. In only 7 percent of the incidents was the child

supervised by another child, or unsupervised.

The 2-year-olds represented 39 percent of poisoning by external medications, and 46 percent of accidental poisoning by internal medication. The next highest frequency of poisoning by medication occurred among 3-year-olds.

Chemicals classed as cleaning and polishing agents, pesticides, petroleum distillates, and paints and solvents are particularly hazardous to 1-year-olds, who represent roughly half of the cases of poisoning by these commodities. The 2-year-olds swallowed these poisons more frequently than the 3-year-olds.

While children in their third year, and older, are less inclined than their juniors to swallow poisons, they show a greater preference for medications. More than half of the poison incidents in this age bracket resulted from self-administered internal medications, although they represent only a moderate share of the total cases of poisoning by medications.

On the other hand, children under 1 year represent the highest proportion of poisoning by external medications. They also claim the highest proportion of poisonings by pesticides.

Males are poison victims more frequently than females up to the age of 10 years. After the age of 15, females are the more frequent victims.

Aspirin, predominantly the so-called "baby-type," was the drug of choice in half of the incidents of poisoning by internal medication. It accounted for about 20 percent of all reported cases. No other chemical was reported to have such singular prominence.

The case fatality rate was 2.1 percent per 1,000 ingestions. For petroleum products it was 10, and pesticides 3.4.

Habitual Drinkers Highway Hazard

Addiction to alcohol as a highway hazard was one of the factors which

led Pennsylvania's Department of Health in 1958 to set up a section on traffic epidemiology in its division of behavioral problems, according to Dr. C. L. Wilbar, Jr., State secretary of health. The medical chief of the section has undertaken to develop public health factors in the establishment of physical and mental standards for licensing of drivers. In this connection, he is acquiring data on the influence of alcohol on driving ability and studying records of accident repeaters.

Although alcohol in the bloodstream of a driver, passenger, or pedestrian has been incriminated as a major factor in highway injuries and deaths, Dr. Wilbar remarked that punitive and educational activities seem not to have been effective in discouraging the mobile drinker.

The literature available on the subject, slender though it is, he said, indicates that the habitual alcoholic rather than the casual drinker is the major offender. In confirmation of this conclusion, he said, of 241 patients treated for alcoholism in a State mental hospital in Pennsylvania, 12 within 4 years before admission were convicted of driving under the influence of alcohol. As a percentage, these alcoholics had 17 times as many such convictions as the general population of drivers.

Restriction of licensing, rather than revocation, he said, is the recommended policy for regulation.

In preparing drivers' licensing standards for the State department of revenue, the health department has enlisted support of subcommittees of the State medical society, dealing with general medicine, cardiovascular diseases, neurologic disorders, visual standards, auditory standards, orthopedic standards, mental health, and drugs and chemicals. These categories were employed originally in a New York University symposium on accident prevention in December 1956.

Other sources of reference used included the American Medical Association guide on determining fitness to drive a motor vehicle, and testimony before the Subcommittee

on Traffic Safety, Committee on Interstate and Foreign Commerce of the House of Representatives of the 84th Congress, 1956. Except for certain psychological recommendations still under development, and certain standards for vision, the recommendations of the medical society have been approved in principle. Different standards apply to passenger transport operators, commercial operators, and private automobile drivers. Physical examinations for drivers are recommended on application and thereafter at the ages of 30, 40, 50, 60, and every 5 years thereafter.

Skin Radiation Reappraised

Fifty board-certified dermatologists collaborated in a survey organized by Dr. David Goe Welton, Charlotte, N.C., and Prof. Bernard Greenberg, School of Public Health, University of North Carolina, in a 1958 study of the use of ionizing radiation for treatment of skin conditions.

With records of 27,000 visits by patients, it was learned that ionizing radiation was used to treat almost a fourth of the conditions diagnosed. The 12 diagnoses most often treated by radiation were keloid, anogenital pruritis, neurodermatitis anogenital, other localized neurodermatitis, eczematoid dermatitis, dyskeratosis, epithelioma, chronic dermatitis venenata, fungus infections, psoriasis, all types of acne, and herpes zoster. Radiation uses increase gradually with the age of the patient.

A rather consistent uniformity of opinion was found as to the specific diagnoses for which radiation therapy should be used. The number of these conditions is considerably less than it was 10 years ago.

It was concluded that the selective use of radiation and the application of devices for increased protection of the patient support the belief that "there is no threat to the public health" from the use of ionizing radiation by dermatologists.

Toxoplasmosis Prefers Man to Mouse

The sea around us, according to Don Eyles, Public Health Service scientist, may be toxoplasmosis, perhaps the most frequent parasitic infection of this world.

Although widespread in man and many other warm-blooded animals, only in the last generation has human toxoplasmosis been recognized. Most adults carry antibodies which

probably indicate prior experience with the infection. Eyles said there is little reason to doubt the specificity of the dye test which supports this estimate of prevalence.

Nevertheless, the mode or modes of transmission of the parasite, a protozoan of uncertain affinities which grows intracellularly in a variety of tissues, is unknown. Infections are usually benign, he said, but are occasionally severe and even fatal.

The only epidemiological charac-

teristics of the disease suggested by Eyles apply to temperature, moisture, and family. No clear-cut economic, social, or environmental factor has been established, however.

Eyles suspects that studies of animals may provide the best clues to the disease. For example, he mentioned cats as having a high prevalence, whereas laboratory mice, which are quite susceptible to the parasite, rarely have spontaneous infections.

Seasonings and Flavorings Safe for Use

Safety clearance of most of the natural seasonings and flavorings that the housewife uses in her kitchen and of many others that go into her packaged foods was provided in a food additives regulation issued by the Food and Drug Administration in January 1960. More than 150 naturally derived seasonings and flavorings are listed as safe for use in food on the basis of the findings of qualified experts throughout the country.

Cinnamon, cloves, nutmeg, thyme, and vanilla, are included as well as those familiar to the gourmet or the commercial food processor such as coriander, mace, savory, and extracts of balsam of Peru, spike lavender, wild cherry bark, and ylang-ylang.

The list was developed from the comments of food scientists on an original list of natural flavors published in the April 21, 1959, Federal Register. Manufacturers who use these flavors need not furnish further proof of their safety.

Information on safe usages for seven flavoring substances is not sufficiently well established among qualified experts to permit a formal determination by the Food and Drug

Administration that they are "generally recognized as safe." These are quinine, red and yellow cinchona barks from which quinine is derived (all three are used in so-called "tonic" carbonated water), two forms of orris root (having minor food use as a supplemental flavor), and wintergreen and methyl salicylate (chemically identical forms of the same flavor).

Wintergreen and methyl salicylate have been used in confectionery for many years and there is no evidence that the very small amount required to flavor candy is hazardous. However, the agency has deferred a determination on their safe use until additional data from current laboratory studies of methyl salicylate are available, possibly in a year. Meanwhile, action will not be taken against candy or other foods flavored with methyl salicylate or oil of wintergreen in the amounts customarily used for these substances.

Concerning quinine, cinchona, and orris as flavorings, it is expected that levels of safe usage will be established by regulations issued in response to petitions from interested users.

Signs

and

Symptoms

of trends in public health

Alcoholics employed in the transportation industry as locomotive engineers, as pilots, or as truck or bus drivers are a public hazard, says Dr. Marvin A. Block, in an editorial in the *Journal of the American Medical Association*, August 29, 1959. He recommends cooperative efforts by labor, management, and medical societies to exclude heavy drinkers from these and other positions where inaccurate or faulty judgment due to alcohol endangers the lives of passengers.

"You're on your own if a national emergency occurs" warned Dr. Caruth J. Wagner, acting as spokesman at a recent joint meeting of the Disaster Medical Care Committee of the American Medical Association and the Division of Health Mobilization of the Public Health Service.

Survival after a thermonuclear attack would depend upon the individual's ability to take care of himself for a period anywhere from 18 hours to 2 weeks, Dr. Wagner said. "Everyone should know how to per-

form lifesaving measures to stop bleeding, give artificial respiration, and treat shock," he continued, adding that people must also know how to assure themselves and their families of safe water and food supplies, general nursing care, and personal shelter and sanitation facilities.

The AMA committee requested the meeting as part of a series of briefing sessions being scheduled throughout the United States. Dr. Wagner is chief of the Division of Health Mobilization, Public Health Service, which was established May 1, 1950, for the purpose of investigating the health and medical needs of the Nation in time of emergency and directing a program to meet these needs. He explained that his statements were premised on the capabilities of modern weapons to cause millions of casualties and to completely disrupt all materials and facilities involved in day-to-day living.

Career opportunities in health were brought to the attention of high school and college students, guidance advisers, and parents last November in Pennsylvania.

The project was co-sponsored by the Pennsylvania Department of Health, Pennsylvania Medical Society and its auxiliary, the Pennsyl-

vania Public Health Association, the Pennsylvania Health Council, and other State and local health agencies.

Governor David L. Lawrence signed a proclamation. News articles, television spots, and radio announcements were distributed to all newspapers, and television and radio stations. Community activities included panel discussions at school assembly programs, community meetings, and parent-teacher association meetings; distribution of printed materials; announcements during school sports events; tours through hospitals, water supply systems, and health centers; reports in school newspapers; and the formation of health career clubs.

Carbon monoxide from the stacks of a steel mill in Weirton, W. Va., last September hospitalized 13 persons a block away.

Poliomyelitis Immunization House to House

WILLIAM A. ALLEN, M.P.H., AND MICHAEL J. BURKE, M.A.

WHAT results can be obtained by a house-to-house poliomyelitis campaign among "hard-to-reach" groups?

This question had been raised a number of times by staff members of the Philadelphia Department of Public Health. When in the summer of 1959 it appeared that immunization was lagging in sections of the city where poliomyelitis incidence was highest, it was decided to conduct a house-to-house program through the use of four mobile teams.

A number of extensive immunization programs had been conducted in prior years in Philadelphia. As in many other communities throughout the country, the poliomyelitis immunization program was initiated in April 1955, as soon as the Salk vaccine was released.

The first phase was directed toward inoculating children in the first and second grades of public, parochial, and private schools. From the inception of this program, there was excellent cooperation between the Philadelphia Department of Public Health and the medical divisions of the public and parochial schools.

Every year since 1955, the schools have conducted intensive inoculation programs with vaccine furnished by the health department. Age restrictions were gradually modified so that, eventually, the immunizations were made available to children in all grades. The health department provided the personnel for the administration of the parochial school program. The public schools, however, supplied their own personnel for their program.

Mr. Allen is director of the division of health education and Mr. Burke, statistical epidemiologist, Philadelphia Department of Public Health.

All vaccine used by the schools in 1955, 1956, and 1957 was supplied by the health department either through its own budget or by allocation from Federal or State sources. In 1958 and 1959, however, in addition to the city supply, the Philadelphia Chapter of the National Foundation gave the department 100,000 cc. of vaccine, some of which was used by the schools. In the spring of 1959, the public schools purchased additional vaccine for their use.

In the summer of 1956, again with the cooperation of the schools, the health department organized 10 teams, 1 in each of the 10 health districts into which the city is divided. These teams moved from one school to another each day. They inoculated 110,000 children. The teams worked in 113 public and parochial schools immunizing children under 15 years of age and expectant mothers. By working through the schools to bring the program to the people in their neighborhoods, great numbers of previously unvaccinated persons were reached. At the same time, daily inoculations were given in the health centers.

In 1957 the health department, the Hospital Council, and the Philadelphia County Medical Society jointly conducted inoculation clinics in 10 private hospitals strategically located throughout the city. These clinics were held on 4 Saturdays selected so that an individual could receive at least two inoculations.

Members of the county medical society volunteered their services to staff the clinics. Volunteer clerical workers from the local chapter of the National Foundation and hospital and health department personnel completed the clinic staffs. During this phase of the program, which provided immunizations for persons 40

Carbon monoxide from the stacks of a steel mill in Weirton, W. Va., last September hospitalized 13 persons a block away.

A crowd forms around a team giving inoculations on a Philadelphia street corner

trucks toured the neighborhoods announcing the free inoculations in the clinics. All of these efforts were directed at getting residents to come to the established clinics.

Because of the wide variety in the backgrounds of residents of the city including economic, cultural, and ethnic differences, a number of different motivational approaches were used, especially among the "hard-to-reach" groups.

Within a few weeks it was evident that this program, aimed at providing free inoculations to children under 7 years of age and expectant mothers, was lagging despite the intensive efforts to encourage residents to participate.

With the poliomyelitis season approaching

and realization that the "hard core area" had not been reached adequately, plans were made to bring the program to the people through the use of mobile teams operating on a door-to-door basis in districts 5 and 6.

Several planning meetings of representatives from public health nursing, epidemiology, health education, and other divisions were held to pave the way for the kickoff of the new program.

Four teams were organized to work in these districts. The teams traveled in station wagons which were equipped with vaccines, syringes, and other supplies. Banners announcing the free injections were prominently displayed on the vehicles, and loudspeakers were mounted on

years of age and under, almost 75,000 persons were inoculated.

On the first Saturdays of February and March 1958, inoculations were offered at 10 public and parochial school sites to persons through 40 years of age. Vaccine, as well as a number of volunteer workers, was supplied by the local chapter of the National Foundation. Most of the staff, however, came from the health department. Because inclement weather limited the total number immunized to less than 40,000, the health department had a large amount of unused vaccine. The department made it available to universities, colleges, seminaries, professional schools, and technical and vocational schools.

In the summer of 1958, daily inoculation sessions were held in district health centers for all persons 40 years of age and under. Night sessions for persons in these age groups were conducted during August, September, and October.

In all of these programs the department noted that the response was poorest in areas of the city having the lowest economic standards and the most congested living conditions.

Since 1955, Salk vaccine has been distributed upon request to hospitals for their prenatal and pediatric clinics. In 1959, for example, vaccine was distributed to 36 hospitals and to private physicians for the inoculation of their patients who could not afford the cost of the vaccine. The hospitals and the physicians were required to submit a form for each inoculation administered.

Mobile teams traveled in loudspeaker-equipped station wagons, which also carried supplies

Despite all efforts to raise the immunization level of the city to a satisfactory level, 77 cases of poliomyelitis, including 2 deaths, occurred in 1958. This represented a sharp rise over the previous year and was the greatest number of cases recorded in the city since pre-Salk days. In 1954, there had been 228 cases. The number of cases in 1955 was 42, and in 1956 the number declined to 16. In 1957, only 10 cases were recorded in the city.

Of the 77 cases which occurred in 1958, 39 cases, or 50.7 percent, were in health districts 5 and 6, which had an attack rate of 9.1 per 100,000 population. In comparison, the remainder of the city had 38 cases, or 49.3 percent, an attack rate of 2.1 per 100,000. The overall attack rate for Philadelphia was 3.5 per 100,000 population.

Late in 1958, the department reviewed the effectiveness of the various immunization programs which had been undertaken. Based upon statistical data gathered from school programs, special programs, and district clinics, estimates were made regarding the general immunization status of the city. It became apparent that additional efforts were needed to motivate residents in health districts 5 and 6 to protect their children and themselves against poliomyelitis and to prevent the possible development of an epidemic in the city.

Districts 5 and 6 are bounded by the Delaware and Schuylkill Rivers and extend from Vine Street on the south to Lehigh Avenue on the north. They are characterized by substandard housing, low incomes, and a greater incidence of other diseases such as tuberculosis and venereal disease. These districts also have a higher infant mortality rate than the city as a whole and many other social and economic ills.

Because of the apparent failure to gain response in these districts to the previous inoculation campaigns and the upsurge of poliomyelitis incidence in 1958, most of which occurred in this area, the health department decided to direct its attention to methods aimed at the "hard-to-reach" groups.

Accordingly, early in 1959 special methods were used. Thousands of specially designed leaflets and posters were distributed, volunteers visited homes in the neighborhoods, and sound

In the actual operation, a team sometimes proceeded along a particular street, stopping often to give injections. Frequently, however, it was more advantageous to park the vehicle for long periods and administer the vaccine from a strategically situated parking lot or street corner.

During the 10 weeks that the program was in operation, 37,879 individuals were inoculated. Of this number, 21,326, or 56.3 percent, received their first inoculation; 7,297, or 19.3 percent, their second; 5,348, or 14.1 percent, their third; and 3,908, or 10.3 percent, their fourth. By age distribution, 12,363, or 32.6 percent, were under 7 years of age; 6,777 or 17.9 percent were 7 through 14 years; 1,823 or 4.8 percent were 15 through 18 years; and 16,916 or 44.7 percent were 19 years of age or older.

Since more than 75 percent of the inoculations were given to preschoolers and to persons more than 19 years of age, the program was effective in reaching susceptible age groups as well as groups in which the immunization level was considered to be extremely low.

Although it is felt that the house-to-house approach was successful in immunizing many people who would not otherwise have been reached, several disappointments were encountered. During the campaign, eight cases of paralytic poliomyelitis and one nonparalytic case occurred in Philadelphia, all of them in health districts 5 and 6 where the mobile teams were operating. The fourth, fifth, sixth, seventh, and eighth cases occurred almost within the shadows of the mobile units. None of the persons with the disease had availed themselves of the vaccine.

The success of the campaign, however, is indicated by the fact that the incidence of polio-

. . . and in New York City

Two mobile clinics began giving free poliomyelitis inoculations in August 1959. The clinics, set up in trucks loaned by the city's civil defense office, operated from 1 to 6 p.m. for 10 weeks and moved to a new location each day. Above: At 125th Street and Lenox Avenue health department staff members register those to be vaccinated. Right: Harlem children wearing sandwich boards help to publicize the clinic's visit in their neighborhood.

At the district health center the teams laid final plans for the evening's operations

the roofs. Personnel for each team consisted of a physician to give the injections, a public health nurse to go from door to door to tell residents about the availability of the inoculations and to answer questions, a graduate nurse to fill syringes and assist the physicians, a health educator to organize in advance and coordinate a volunteer corps to assist in the home visits, a clerk to register persons requesting inoculations, and a disease control investigator or sanitarian to drive the station wagon and to make announcements over the loudspeaker.

The local chapter of the National Foundation supplied funds to rent sound equipment and produce the tape recordings which were used in addition to live announcements. A well-known soft drink company provided containers to refrigerate vaccine, and a sound equipment company provided additional loudspeakers.

The newly constructed health center in district 6 was selected as headquarters for the program. This center has an excellent physical plant with adequate storage facilities. It has a large parking lot which permits easy loading of vehicles, and in addition, it is convenient to

good transportation facilities to all parts of the city, which facilitated the travel of personnel staffing the program.

The house-to-house program was initiated July 6 and continued through September 1. Hours of operation were between 5:30 and 7:30 p.m., Mondays through Fridays. Because teams continued to work until everyone wishing an injection had been immunized, the teams frequently did not return to the headquarters until 9 p.m.

In order to speed the registration procedure, no forms were filled out for adults. For children under 21, it was requested that parents complete a parental consent form. When parents were unable to come to the mobile unit, children were given a parental consent form and were immunized when they returned the completed forms.

When the house-to-house program began, immunizations were offered only to children under 7 years of age and expectant mothers. Because of the difficulty of limiting the inoculations to this age group, the program was expanded to provide immunizations for persons of all ages.

PROBABLY the most prevalent bacterial pharyngitis of humans today is that caused by beta hemolytic streptococci of group A. The clinical diagnosis of such an upper respiratory infection, although reasonably good in some instances (1), depends on a clinical picture which is not characteristic in all age groups (2, 3). Adjunct laboratory aid, by isolation of the causative organism, is therefore valuable in determining and evaluating therapy and its duration and is a necessity for intelligent control and prophylaxis. The latter measures apply not only to the streptococcal infection, but even more importantly, to the nonsuppurative sequelae of rheumatic fever (4) and acute diffuse glomerulonephritis (5).

Procedures for isolating bacteria are not available to the average physician or to health officers in some areas. Even when these pro-

The study was supported in part by a grant from the D. A. Beattie Fund. (Manuscript received for publication October 7, 1959.)

myelitis in Philadelphia in 1959 was approximately 73 percent under the incidence for 1958. For the Nation as a whole the incidence of poliomyelitis was up almost 42 percent in 1959.

It seems evident that the house-to-house approach, by providing immunizations for "hard-to-reach" groups in their neighborhoods, played a prominent part in cutting the toll of poliomyelitis in Philadelphia.

Summary and Conclusions

Since 1955 when the Salk vaccine was released, the Philadelphia Department of Public Health has conducted a continuing poliomyelitis immunization program which has had a number of different phases. Cooperating in these various phases have been the public and parochial schools, the Philadelphia County Medical Society, the hospitals, and the local chapter of the National Foundation.

During the program, many of the well-established techniques to motivate residents to become inoculated were used. The department staff noted that, although response to various phases of the program was great in many higher income areas of the city, the response in certain of the lower income, highly congested areas was almost invariably poor.

Although the incidence of poliomyelitis was relatively low in 1955, 1956, and 1957, an upsurge of the disease occurred in 1958 when there were 77 cases, including 2 deaths. An analysis of the immunization situation made by the department staff late in 1958 led to the conclusion

that a renewed effort was required to increase participation in the program among the residents in health districts 5 and 6, the area in which most of the 1958 victims lived.

A special program was instituted early in 1959 to encourage the groups most susceptible to poliomyelitis to become immunized at the regular health department clinics in districts 5 and 6.

When this program lagged in the spring of the year, the health department staff, realizing that adequate immunization had not been gained and faced with the threat of a possible epidemic or outbreak, organized a special house-to-house immunization campaign in which mobile teams toured the neighborhoods in health districts 5 and 6 for a 10-week period, July 6 through September 11.

During this effort, 37,879 persons were immunized. The results of the house-to-house campaign revealed that this type of direct approach, particularly to groups which do not respond to the usual approaches, can be of great value in increasing participation in immunization programs. Of the people responding to the campaign, the majority were in the age groups most susceptible to poliomyelitis and in which the immunization level was particularly low.

Detailed planning and close cooperation of all health department organizational units, as well as close cooperation with groups in the community, are essential in any program of this type.

Kurlander, Assistant Surgeon General

Arnold B. Kurlander, M.D., formerly deputy chief of the Bureau of Medical Services, Public Health Service, has been named Assistant Surgeon General. He will assist the Surgeon General on current program matters, facilitate communications between the four bureaus of the Service and the Surgeon General's office, and expedite the handling of program aspects of operating problems.

blood agar (fig. 1) which was incubated immediately at 37° C. and designated as the control culture by source laboratory W, X, or Z.

The other swab was streaked heavily back and forth onto a filter paper strip in an opened kit as described (6,7). The strip was air dried 3-5 minutes before the kit was refolded, placed in a Manila envelope, and mailed or transported to a receiving laboratory, *p*, *q*, *r*, or *s*. Two of the source laboratories in California also acted as receivers. The other receiving laboratories were in Georgia and Maryland.

After 2-10 days the filter paper strip was removed from the kit and plated (fig. 2), except for strips which were plated after 5 to 21 days by receiver *s*. In plating, the FPS was removed from the kit and placed inoculum side down on the blood agar surface without prior treatment of any kind. Before the plate was inverted for incubation, the plated strip was inspected to see that it had absorbed moisture from the medium. Any part of the strip which was dry was pressed gently against the surface of the agar until it appeared wet. After 6 hours' incubation at 37° C., the filter paper strip was removed from the primary plate and placed inoculum side down on a second or replica plate. Both replica and primary plates then were incubated 18 hours at 37° C., making a total of 24 hours for the primary plate.

The visual reading was then made with the strips removed so that isolates could be picked. If the growth was heavy, only the primary plate had discrete beta hemolytic colonies, the replica plate having confluent lysis. Occasionally, if growth was very light the primary plate had no lysis, but this finding was exceedingly rare. Plating was on 10 percent defibrinated sheep blood agar in laboratories *p* and *r* and on 3-5 percent defibrinated rabbit blood agar in laboratories *q* and *s*. Three of the laboratories were relatively unfamiliar with the FPS technique.

Cultures from paired swabs were designated by number. In order to eliminate bias, the controls and filter paper strips were matched as pairs only after final reports were received. Each of the four receiving laboratories was sent 34 inoculated FPS kits by each of three source laboratories, 408 in all. Eight kits were reported lost, leaving 400 paired cultures in the

study. Of each set of 34 kits, 17 were estimated to be negative and 17 positive on the basis of preliminary visual reading of the control cultures at the source laboratory.

From all positive cultures (control and filter paper strip) isolates were identified by serologic grouping (9). At two laboratories (*q* and *s*) grouping was done with antisera from the Communicable Disease Center, Public Health Service, Chamblee, Ga. All other grouping was done by laboratory *r* with antisera from a biological supply company (Difco).

Two statistical estimates on pooled data are presented, the difference between two proportions and twice the standard error of the difference between these proportions. The difference between the two proportions is considered significant only if it is more than twice the standard error (10).

Recovery by Streptococcal Group

Group A streptococci were isolated from control cultures and cultures of filter paper strips.

Figure 2. Plating a filter paper strip

The filter paper strip is placed, inoculum side down, on the surface of the blood agar medium. The strip absorbs moisture from the medium and is plated directly upon removal from the kit without treatment of any kind.

cedures are available, methods of transporting pharyngeal materials to a laboratory are cumbersome and do not always assure the arrival of viable bacteria. To obviate some of these difficulties, a method for mail transport of throat swabbings on sterile filter paper in enclosed kits was recently developed (6). The method appears reliable for use in the diagnosis of group A streptococcal infection: beta hemolytic streptococci, 80 percent of which were of group A (7, 8), were recovered by culture after 2 to 10 days in transit on the filter paper strips (FPS). The results of testing more than 2,500 children compared favorably with those obtained from immediate culturing, by usual techniques, of simultaneous paired control swabs.

The present study was made to test further the FPS method for reliability, reproducibility, effects of transport distance, and other factors on the isolation of beta hemolytic streptococci from pharyngeal swabs.

Clinical Material

A total of 400 paired throat swabbings were supplied by three source laboratories. W, X, and Z, located in California. Laboratories W and X obtained 264 of the paired swabbings from patients in the closed population groups at a private pediatrics office, at the outpatient pediatrics clinics, and in a cooperating county health department (7).

The remaining paired swabbings were supplied from a field trial in which more than 500 paired throat cultures were obtained from children or their parents in less than 3 hours. This field trial was conducted at an open county clinic during a 1-day Salk vaccine inoculation program. The microbiologists on temporary assignment from laboratory Z found that the 500 paired cultures were not obtained by the method proposed and the filter paper strips were not air dried 3-5 minutes. Of these 500, the first 136 controls and the paired filter paper strips are reported for comparison with data obtained by the proposed method.

Methods

To obtain paired throat cultures, simultaneous swabbing was employed. Two throat swabs

Figure 1. Method of streaking blood agar plate

were held in one hand and thoroughly rotated over the pharynx of the patient, care being taken to obtain an entirely satisfactory specimen. Without delay, one swab was dilution streaked onto 10 percent defibrinated sheep

miles or less from the source laboratories in California. Agreement for group A isolates was 86-100 percent among all receivers (*p*, *q*, *r*, *s*) and all sources (*W*, *X*, *Z*), percentage estimates being based on the total negative controls. For negative controls, percentage figures below 100 percent indicate that group A streptococci were isolated from the matched filter paper strip cultures. For positive group A controls, laboratories receiving FPS from sources *W* and *X* were in approximate agreement, with a record of 74-86 percent recovery (table 3). This 74 to 86 percent range in percentage recovery is no greater than would be anticipated from prior investigations of throat flora (11,12). In the investigations cited, variability was so great that it was deemed impossible quantitatively to interpret the growth on throat cultures.

In contrast to the agreement with sources *W* and *X*, the percentage agreement for positive group A controls varied from 0 to 91 percent among laboratories receiving FPS from source *Z*. These filter paper strips were not

obtained under the conditions described for the study nor were they air dried. The set of 34 kits sent receiver *q* had no paired positive controls, the set sent receiver *p* was estimated to consist only of positives, and the 34 kits sent receiver *s* showed no growth when the FPS were plated at 15 days, or 5 days after the designated holding period of 2-10 days.

There was remarkably close agreement (100 isolations from filter paper strips, 106 isolations from controls) in the recovery of group A streptococci, regardless of holding time, source, location of receiver, and previous use of the technique (tables 1 and 2).

Groups B, C, and G beta hemolytic streptococci, on the other hand, apparently have been recovered in significantly greater percentages from the control than from FPS cultures (tables 1 and 2), but inspection of the data results in reservation of an opinion. Within group C, only about 25 percent and within group B or G only about 40 percent of the streptococci isolated were from filter paper strip cultures (table 1). However, a review of

The percentage recovery was the same, although controls were plated at once from throat swabbings, while inoculated FPS were in transit or were held 2-17 days prior to culturing. Of the 206 group A strains recovered, 106, or 52 percent, were from controls, and 100, or 48 percent, were from filter paper strips (table 1). Basing the percentage estimate for group A on the 400 cultures reported by receiving laboratories, recovery was 25 percent from FPS and 26.5 percent from controls. These percentages are not different; on pooled data the difference between proportions equaled 0.015, and twice the standard error equaled 0.062.

The transit and holding period prior to culture of the 100 filter paper strips from which

group A streptococci were isolated was 2-17 days (table 2). Within the designated parameters (2-10 days holding time) of the study, 87 group A streptococci were isolated from FPS and 88 from control cultures plated immediately, a striking record. Due to the small numbers plated each day and to the finding that one set of 34 filter paper strips had no growth on culture after a transit and holding period of 15 days, statistical estimates are not considered valid for percentage recovery based on a single day or on time periods beyond the anticipated 2-10 days before plating (table 2).

The percentages in table 3 show that group A streptococci survived equally as well when the FPS were shipped 2,500 or 3,000 miles into Maryland or Georgia as when shipped 400

Moisture, Drying Surface, and Temperature

Two previous studies indicate that a greater number of recoveries of beta hemolytic streptococci can be obtained upon culturing filter paper strips, air dried after inoculation with these organisms in throat swabbings, than can be made from similarly inoculated strips which are not air dried before a 2-10 day transport period (6,7). In these two studies the effect of temperature was not explored.

Working in Zurich, a team of three investigators (13) found recovery of *Streptococcus pyogenes* following drying was improved if the relative humidity was very low or zero. A room temperature of 20° C. favored recovery, whereas temperatures of 30° and 37° C. decreased the colony count on culture following drying. The three investigators demonstrated that, after drying, 10 to 80 times as many streptococci remained on a glass coverslip as were washed free by 4 minutes of shaking followed by 10 minutes of soaking in the rinse water. This difficulty in removal of organisms from glass is comparable

to removal from cotton (14). The successful use of filter paper strips for transport of streptococci is in conformity with the finding that viability and recovery of streptococci depend not only on drying but on inoculating on a rough surface and culturing the transport material itself rather than streaking or rinsing it (13).

Further documentation of the successful recovery of group A streptococci from filter paper strips, upon culture after a 2-10 day transit and holding period, is unnecessary. The equivalence of control and FPS techniques is evident in all group A tabulations.

Summary

The filter paper strip technique for transport and holding of throat swabbings for subsequent culture of beta hemolytic streptococci further was tested by investigators in five collaborating laboratories. Of these five, located in Georgia, Maryland, and California, the three

the original records shows that 46 percent (31 of 67) of all the FPS paired with groups B, C, and G positive controls were from source Z and were not air dried. For this reason tabulation by holding time before plating does not yield additional useful information on these groups (table 2). Insufficient data were obtained in the study to support a valid conclusion on the efficiency of the filter paper strip technique for use in recovery of group B, C, or G streptococci. Additional study is warranted.

Recovery by Source and Receiver

Sources W, X, and Z. Of all paired cultures 57 percent, or 227, were negative controls and 43 percent, or 173, were positive controls (table 4). There were 306 positive isolates, of which 33 percent, or 133, were from cultures of filter paper strips. This is significantly less than the percentage of positive controls (difference between proportions on pooled data equaled 0.100 and twice the standard error equaled 0.067). Interpretation of this difference is complicated by conditions which obtained at source Z.

The pattern of agreement of reports on

matched filter paper strip and control cultures for the entire study (table 5) is somewhat similar to the pattern of agreement of group A isolation (table 3). For the entire study there is 81-100 percent agreement for FPS reports matched with negative controls. The 81 percent indicates that 7 of the filter paper strips from which positive cultures were obtained were matched with negative controls (sources W and X, receiver *p*, table 5).

Sources W and X compared with Z. For positive controls the percentage agreement was equivalent for sources W and X regardless of receiver (74-81 percent), but this is not the case for source Z (0-64 percent, table 5). There is no difference between the percentage of positive isolates from air dried filter paper strips (40 percent) and from controls (45 percent, table 4, sources W and X). The difference between proportions on pooled data equaled 0.05 and twice the standard error equaled 0.086.

There is a difference in recovery if the inoculated FPS are not air dried. For instance, from source Z percentage recovery from strips is only half that from positive controls, 20 and 40 percent respectively (table 4).

fects of high humidity or high temperature air drying is essential, even if a longer period is required, but air drying will not insure satisfactory recovery of streptococci if the swabbing is unsatisfactory.

Use of Heptachlor on Crops Banned

The use of the pesticide heptachlor under conditions which leave residues on harvested crops was prohibited on January 19, 1960, by the Food and Drug Administration, through the rescinding of a regulation permitting small residues on harvested food and forage shipped interstate.

New scientific data have shown that in addition to residues of heptachlor, a breakdown product, called heptachlor epoxide, is present after heptachlor treatments, and that residues of epoxide appear in meat and milk when forage containing it is fed to experimental meat and dairy animals. No residues of heptachlor itself have been found in meat or milk. How much epoxide may be present under varying conditions and the toxicity of the substance have not been determined. No action will be taken against crops already treated within previous regulations.

² No growth.

in California served as source laboratories. Using two swabs for simultaneous swabbing on each patient, each source laboratory immediately inoculated a control culture and a paired FPS. Each source sent a set of 34 inoculated filter paper strips to each of four receiving laboratories. Of the FPS in each set, one-half were estimated to be positive on the basis of preliminary reading of controls. In all, 400 filter paper strips were received and held for variable time periods. From both controls and filter paper strips 306 strains of beta hemolytic streptococci were isolated, 305 of which were groupable. The findings were tabulated by streptococcal group, percentage agreement by positive and negative controls, and by source and receiver as well as by time held prior to plating.

The filter paper strip technique proved to be highly satisfactory for transport and holding of group A streptococci. Of the 206 strains of group A streptococci isolated, 106 were from controls and 100 were from FPS. This record of recovery, 52 percent from controls plated at once and 48 percent from filter paper strips held or in transit 2-17 days before culture, is

remarkable in view of the geographic distribution of receiving laboratories and the fact that three of four receiving laboratories were relatively unfamiliar with the technique. For group A isolates, source and receiver achieved equally good percentage agreement with respect to negative controls and to recovery from filter paper strips air dried after inoculation.

Data on percentage recovery of groups B, C, and G streptococci by the filter paper strip technique are inconclusive. Half of the FPS paired with controls positive for B, C, or G were not air dried and one-sixth were plated at time intervals beyond the 2-10 day period designated for the study. Of 100 B, C, and G isolates, 33 percent were from FPS and 67 percent from controls. Any conclusion as to recovery is complicated by the conditions which obtained for those filter paper strips cultured and matched with controls positive for these groups of beta hemolytic streptococci, and additional studies are warranted.

Attention is directed to the necessity for adhering strictly to the described technique for throat swabbing and for handling filter paper strips. Because of the possible deleterious ef-

Diagnosis of Streptococcal Infections

It has been estimated that about 2 million people living in the United States today have already had, or will develop, rheumatic fever at some time during their lives. Of these, more than 500,000 will probably die because of the rheumatic process or some complication developing directly from it.

Rheumatic fever most often strikes children between the ages of 5 and 15, and the resulting rheumatic heart disease causes about 50 percent of all heart disease in this age group. It is estimated that in the 5- to 19-year age group in this country there is a current annual incidence of about 60,000 cases of rheumatic fever. About half of these are recurrences, and the remainder are first attacks. It is the recurrent attacks of the fever which cause the actual damage to the heart itself.

While the past 40 years have shown a marked reduction in rheumatic fever mortality, the problem is far from solved. In 1957, rheumatic fever and rheumatic heart disease combined to cause the deaths of about 20,000 in the United States. However, by the application of what is currently known about these diseases, some real progress has been made.

What causes rheumatic fever is not fully understood, but research has shown that cases usually begin with a streptococcal infection—primarily of the throat. The specific pathogen has been identified as group A beta hemolytic streptococci.

Antibiotics can eliminate streptococci, and effective prophylaxis can prevent the secondary attacks of rheumatic fever. Indeed, penicillin prophylaxis appears to be accelerating the decline of rheumatic fever.

First attacks of rheumatic fever can be prevented through prompt treatment of streptococcal infection which entails the use of an antibiotic (preferably penicillin) for a period of 10 days. But therein lies the physician's dilemma. A "strep throat" cannot always be

distinguished clinically from sore throats caused by other organisms, but every "strep throat" is a potential case of rheumatic fever.

Since there are many objections to indiscriminate penicillin therapy, the physician usually considers it advisable to delay treatment for 2 to 3 days until the causative agent can be identified by a throat culture. He is repeatedly forced to decide whether to postpone treatment until a definite diagnosis is made, and perhaps save the patient some money, as well as lower the risk of a future penicillin sensitivity, or to treat the infection with penicillin immediately on the chance that it is "strep."

To date, prevention of the first attack has been almost impossible to achieve, since there was no quick, certain way for the physician to identify streptococci. Now the fluorescent antibody technique has provided a means for overcoming this obstacle.

The fluorescent antibody test works this way: Antibodies for a specific disease are stained with a fluorescent dye and then dropped onto a slide which has been smeared with material taken from the patient whose disease is to be diagnosed. If the smear contains a germ for which the antibody is specific, the antibody will immediately attach itself to the germ. When the liquid containing the antibody is washed off the slide, the antibody and the germ will remain, and, under ultraviolet illumination, a greenish fluorescence resembling minute neon lights will show up on the slide. If the germ is not present in the specimen, the antibody will wash off the slide along with the liquid that contained it.

The use of the technique by State laboratories as a diagnostic aid to physicians must necessarily be a gradual, natural growth. Lack of trained personnel is only one of many problems connected with initiating such a service program in a State or community. Other difficulties involve submission and transportation

INTERNATIONAL MAIL POUCH

Regionalization in Paraguay

The 7-month course to train auxiliary nurses in Encarnación was the first fruit of our efforts to demonstrate regionalization. It was the first full-time training for health personnel ever offered outside the capital of Paraguay. The 16 students will complete 1,050 hours of instruction and supervised practice. This is to be a permanent program with one such group being prepared in Asunción, the capital, and other groups in three regional health centers.

—ROBERT T. SCHOLES, M.D., *chief, health and sanitation division, U.S. Operations Mission, Paraguay.*

Cost Cutting

Mounted on motoreycles, two sanitary inspectors did the work of five by completing in 7 months their routine inspections as well as special survey work over an area of 2,000 square kilometers of Surinam. The motorcycles cost about half the salary of a single inspector.

—ROBERT BREWER, *former acting sanitary engineer, U.S. Operations Mission, Surinam.*

Santa Teresa

The new health center in Santa Teresa, Nicaragua, has sparked civic improvements. Even before all the equipment was installed, other changes were planned: a new marketplace and park, and improved water supply and garbage disposal systems. The mayor, the village priest, and the school authorities are most cooperative, and the villagers themselves are enthusiastic.

The staff of the Santa Teresa center and the second new center in Diriá were given an orientation course since some of them are inexperienced in this kind of health work. Their responsibilities are

heavy because they are the only medical units in that part of Nicaragua. They designed a basic medical data form which was used to gather information house-to-house in the two communities. The survey's results will serve as a baseline for evaluating the effectiveness of the rural health centers.

Perhaps the most important task they face is to *reduce the incidence of infestations of intestinal parasites*. Of the first 100 people examined at the Santa Tercsa center, 98 were found to be infected, some with as many as four different varieties of parasites. Gastroenteritis is the principal cause of death in Nicaragua.

The supervising sanitarian, with the sanitary engineer consultant and the Ministry of Public Health, worked out a plan for this rural area's excreta disposal. Sanitary latrines combined with the education efforts of the center's staff is expected to show definite results shortly.

—PATRICK J. SULLIVAN, *former chief, and MAHLON H. HAWORTH, former business manager, health and sanitation division, U.S. Operations Mission, Nicaragua.*

Promotion

One of our graduates has become sanitary foreman of the main construction camp of the Brokopondo dam project in Surinam. Two and a half years ago he started to work for us as a day laborer and his technical skill was limited to handtools and driving a car.

After working with the sanitary engineer, he can use a slide rule like an expert, perform chemical and bacterial tests for water treatment, assemble portable purification plants, and put into operation a complete water treatment plant as well as training its staff.

—ROBERT BREWER, *former acting sanitary engineer, U.S. Operations Mission, Surinam.*

Overweight children usually become overweight adults, according to a study, spanning 20 years, of 200 residents of Hagerstown, Md.

Relationship of Excess Weight in Children and Adults

SIDNEY ABRAHAM and MARIE NORDSIECK

THE ADVERSE effects of obesity upon health have been reported in life insurance and epidemiological studies (1-4). These reports have prompted investigators to employ various remedial methods and approaches to obesity (5-9).

The department of nutrition of the Harvard School of Public Health evaluated two approaches to weight control programs: individual counseling and group therapy (10). A 3-year followup showed that a majority of the 147 subjects failed either to reduce or to maintain a reduced weight. Stunkard and McLaren-Hume reviewed the literature of the past 30 years on results of treatment for obesity and found the results to be "remarkably poor" (11). Their own efforts with a group of outpatients were not successful in either reducing weight or maintaining a reduced weight for 2 years after treatment.

Young and others also reported the lack of success in a weight control program, but suggested the importance of childhood excess weight status as one of the factors determining adult excess weight status and of subsequent problems in weight control (12). They found that relative success was achieved in overcoming obesity when it was a recent development in the adult years. Mullin also reported,

in a retrospective study, on the role of childhood obesity in adult obesity (13). He suggested that a persistent childhood obesity is reflected in a large proportion of adult obesity.

Height-weight data on school children examined some 20 years ago in Hagerstown, Washington County, Md., by the U.S. Public Health Service, presented an opportunity for a prospective study of the relationship of the weight status of individuals in childhood and adult years. Previous observations suggesting a relationship between childhood and adult obesity have been based primarily on retrospective studies of obese adults who have been interviewed about the history of their weight status. Childhood heights and weights on record in the Hagerstown sample supplied data that did not rely on memory for testing the hypothesis that obese children tend to become obese adults.

Method

Physical examinations of school children in three elementary schools in Hagerstown were performed during the years 1937-39. These

Mr. Abraham is a statistician and Miss Nordsieck, program adviser in the Heart Disease Control Branch, Division of Special Health Services, Public Health Service.

Coons Receives Lasker Award

A major contributor to progress in public health, Dr. Albert Coons was presented with the Lasker Award at the 1959 meeting of the American Public Health Association in Atlantic City, N.J., in October.

Dr. Coons developed the fluorescent antibody test in the early 1940's with associates at the Harvard School of Medicine, where he is continuing studies along these lines. He has been a career investigator with the American Heart Association since 1953.

of specimens from the physician's office to the laboratory, a system for reporting the results back to the physician, and the maximum number of tests that can be performed by a single technician in any given period. In addition, the necessary equipment—the ultraviolet light source, filters, and special microscope—is relatively expensive and not in plentiful, immediate supply.

Through the following actions, however, the

Public Health Service is helping to extend the use of the test as rapidly as possible:

- Local personnel have been trained by the Communicable Disease Center and equipment left on indefinite loan in the areas that participated in the field tests.

- About 40 Public Health Service physicians assigned to State and local health departments held a special meeting in Philadelphia on October 27, 1959, to determine the best ways in which they could help health departments, medical societies, and heart associations throughout the country to take advantage of the new research avenues which the fast strep test has opened.

- A 2-week training course for laboratory personnel of 12 State health departments was held at the Communicable Disease Center in January 1960.

- Materials and equipment will be lent to laboratories as soon as they have personnel trained to use them.

- Financial assistance is provided through grants from the National Heart Institute for research projects and through State grants-in-aid for purchase of equipment.

Influenza Research Promoted by PHS Committee

Influenza research was encouraged by a meeting January 13, 1960, of the Public Health Service Committee of Investigators, composed of leading authorities on influenza and related diseases.

Committee members agreed to accelerate their own research during 1960 and to encourage long-range studies. All influenza research projects will receive special review at the National Institutes of Health and qualified projects will be approved rapidly.

Among subjects the committee cited as needing study were:

- Assessment of the value of vaccine given in the 1957 epidemic as to its possible degree of protection.

- The present degree of immunity of unvaccinated persons who had influenza in 1957.

- The physiological effects of influenza on cardiovascular and respiratory systems.

- The neuromuscular effects of influenza.

The Committee of Investigators was established on the recommendation of the Surgeon General's Advisory Committee on Influenza Research.

Members of the Committee of Investigators are: Dr. Robert Wagner, University of Pennsylvania, chairman; Dr. George Burch, Tulane University; Dr. Fred M. Davenport and Dr. Thomas Francis, University of Michigan; Dr. Ivan Bennett, Johns Hopkins University; Dr. George Hirst, Public Health Research Institute of the City of New York, Inc.; Dr. Maxwell Finland, Boston City Hospital; and Dr. Roderrick Murray, National Institutes of Health, Public Health Service.

² 2 in this weight category not sought due to inadequate records.

and 7 because they were not available for interviewing.

Each interviewer carried a measuring stick and a portable scale for height and weight measures. Weight status was measured in terms of relative weight, computed as the percentage deviation of actual weight from average weight for a given height, age, and sex. Average weights were obtained from height-weight tables in the Medico-Actuarial mortality

investigations of 1912 (18) and distributed by the Metropolitan Life Insurance Company. (Revised tables of average weights were a part of the "1959 Build and Blood Pressure Study," recently published by the Society of Actuaries (see p. 266). Publication followed preparation of this paper. An analysis, using these more recent figures, revealed no noteworthy change in the results obtained.)

Distribution for relative weights of adults was not available, but 20 percent or more above average weight was defined as marked overweight (1). Average weight was calculated in a manner similar to that for children whose relative weight values ranged from 95 through 104.

Average age of adults was 31 years. For men, ages ranged from 27 to 36 years, for women, from 26 to 35 years.

Of the 28 interviews with average weight men, 26 were used in the study and 2 for pretesting. One interview with an average weight woman was used for pretesting; all other interviews, a total of 29, were used in the study.

Interviews with 32 overweight men were used in the study and 2 were used for pretesting. Twenty-seven interviews with overweight women were used in the study and one was used in pretesting.

No bias was introduced by attrition since childhood weight status of those who were not interviewed did not differ from those who were. The statistical notes analyze the differences

records, containing height-weight data, are on file in the Public Health Service office in Hagerstown (14). Physical measurement data are available on 977 of the 1,201 boys and 966 of the 1,152 girls examined at ages 10 through 13 years. Cohorts were selected on the basis of available serial height-weight data.

The examiners measured heights without shoes. At the weighing, the children removed shoes, sweaters, or coats, but retained usual indoor clothing.

The weight status of each child was determined by using a relative weight method, defined as the percentage deviation of actual weight from the average weight for a given sex, age, and height. Average weights were obtained from the Baldwin-Wood height-weight tables (15). The distribution of these relative weights is shown in table 1.

Studies of the relationship of obesity to health and disease usually measure obesity in terms of departure of actual weight from a height-weight standard. Obesity or an excess accumulation of fat, therefore, is used interchangeably with overweight or excess weight above standard weight. The limitations of using height-weight tables in this study to determine true obesity were recognized (16). Total body weight is a measure of bone, muscle, and fat, and departure from average weight may be due to one or another or a combination

of these body components. Overweight prevention and control is directed against overweight due to excess fat, primarily attributed to excess food intake over the energy demands of the individual; therefore an effort was made to identify the obese children in the overweight group.

For purposes of weight classification, children were placed in categories of average weight and overweight, and the population was arrayed from largest to smallest by relative weight. Fifty children or approximately 5 percent of the upper distribution of relative weight were chosen for each sex as overweight. The relative weight values of boys ranged from 180 to 116; for girls, from 200 to 124.

This selection of overweight subjects who have extreme relative weight values increases the likelihood that truly obese subjects have been chosen (17). The validity of relative weight measures as an indication of obesity is discussed in the statistical notes.

These findings indicate that, on the average, overweight children are fatter by measurement as well as weight than average weight children.

One hundred children were also selected for the "average weight" classification. Since the distribution of relative weight was skewed toward the higher values, average weight was computed by the median. Relative weights were 98 for boys and 97 for girls. Arbitrarily, we decided to use plus or minus five about 100. Therefore, average weights for the purpose of this study are the relative weight values from 93 through 104. In these categories, there were 425 boys and 290 girls. To select 50 children of each sex for this study, a 12 percent and 17 percent random sample of boys and girls in this weight category were taken.

Table 2 identifies relative weights of the study subjects in each weight classification with regard to the relative weights of the total school population.

Adult Followup

The adult followup was made in the summer of 1958 (table 3). Of the 200 children whose records were selected for the study, 174 or 87 percent were located. However, only 120 were used in this study since 47 were eliminated because of nonresidence in Washington County

between weight status of subjects who were not interviewed and those who were.

Replacements

Subjects who were lost from the initial study group were replaced in order to maintain the original number of 50 males and 50 females in each of the sex and weight categories. Random selections were made from the reservoir of average weight persons so classified originally in the school population. Replacements for the overweight males and females were obtained by selecting the next most overweight from the distribution of relative weight below the upper fifth percentile. By this method, of course, less grossly overweight persons as originally defined were included in the final overweight group. For boys, the relative weights of replacements ranged from 116 to 108, for girls, from 124 to 110. Because relative weights as low as 108 for boys and 110 for girls were included, it was decided to identify two classifications of overweight: moderately overweight, relative weights of 105 through 119, and markedly overweight, relative weight of 120 and more.

Results

Figures 1 and 2 illustrate the trend in weight status from childhood to adulthood of average weight and overweight children. These trends are summarized in tables 4 and 5, which show the comparison between childhood and adult weight status for males and females. For each sex, it is apparent that overweight children tend to become overweight adults more often than children of average weight. Of the 50 overweight boys, 43, or 86 percent, were overweight as adults. Of the 50 average boys, 21, or 42 percent, were overweight as adults. Approximately twice as many overweight boys were overweight adults in comparison to average weight boys. More striking differences in adult overweight status are noted in comparing overweight girls and average weight girls. Of the 50 overweight girls, 40, or 80 percent, were overweight as adults; only 9, or 18 percent, of the 50 average girls were overweight as adults. In both comparisons, the differences are statistically significant: for boys, $\chi^2=19.14$, $D.F.=1$, $P<.001$; for girls, $\chi^2=36.01$, $D.F.=1$, $P<.001$.

It is also apparent from these data that markedly overweight girls and boys are more likely to become overweight adults than the moderately overweight. Seven, or 50 percent, of the moderately overweight girls were average or less than average weight as adults. This observation contrasts with 3, or 8 percent, of the 36 markedly overweight girls who were average or less than average weight as adults. The same findings, but with less difference in percentage, are noted when a comparison is made of moderately overweight and markedly overweight boys; the percentages observed are 22 percent and 4 percent, respectively. These observations reflect the loss of girls and boys in overweight categories who were selected from the upper part of the distributions of relative weight. The data suggest that if, as originally planned, only those in the upper 5 percent of the distribution had been used, more of the overweight children would have fallen into adult overweight categories.

It is quite likely that some persons are in their present weight status because of efforts toward weight reduction or because of the effect of a disability or disease. Some information was gained by asking each person about his usual weight in contrast to his present weight, with the specification that the answer apply to a period at least 6 months prior to the date of interviewing. The results indicated no significant difference in mean relative weights for males and females for the two periods of time.

Discussion

Interest in overweight stems in great part from the role which this factor may play in the etiology of disease, particularly cardiovascular disease. The bulk of the data on weight control lies in the statistics in life insurance studies (1) which have shown repeatedly a significantly higher mortality rate for overweight persons than for persons of average and less than average weight. These findings have been supported also by data from the Framingham heart study conducted by the National Heart Institute of the Public Health Service. In the fourth year of followup of men aged 45-62 years, it was found that overweight was clearly associated with the risk of development

Revised Tables of Average Heights and Weights

In October 1959, the Society of Actuaries published the results of the largest statistical investigation ever attempted in the field of public health, entitled "1959 Build and Blood Pressure Study." The data cover the

20-year experience of 26 large life insurance companies. Five million policyholders are represented in the revised tables of average heights (with shoes) and weights given below.

mortality from such diseases. The effect of weight control on the mortality experience of insured persons has also been reported by life insurance studies (19). These studies have added impetus to weight control as a preventive measure against cardiovascular heart disease. It was found that weight reduction

improved the health outlook for those persons who had lost enough weight to qualify for a new insurance rating. As an example, men originally limited to substandard insurance because they were moderately overweight, upon weight reduction had a lessened mortality rate of 113 percent of the standard, compared with

of coronary heart disease (2). Coronary heart disease incidence rates of overweight men were three times as great as those for men whose weight was below the median weight.

It has been assumed that if diseases, particularly cardiovascular diseases, are induced or adversely influenced by overweight, weight reduction would tend to decrease morbidity and

in terms of relative weight, with the measure of obesity. Chest X-rays were available on 86 boys and 83 girls in the study group. They were read for measurement of fat at the Fels Research Institute, Yellow Springs, Ohio, by Miss Joan A. Haskell. Measurements of fat in the lower thoracic region were taken at the level of the 10th rib on both right and left sides, perpendicular to the fat shadows (20). When X-rays of this particular site were faulty due to improper positioning or extension of the chest beyond the plate, fat measurements were taken at the ninth rib. In a few cases, the X-rays were completely unreadable at both the 9th and 10th rib site, and no measurement of fat thickness was attempted. This was unfortunate since these measurements represented some of the more obese subjects. A complete series of measures was made on two different occasions. Since reproducibility was high, a mean value of fat per individual was calculated.

One approach in evaluating the relationship between overweight and obesity is illustrated in figure 3. This shows the distribution of fat thickness in the lower thoracic region of designated weight categories for boys and girls. It is apparent that the distribution of fat thickness overlaps the weight categories.

Some average weight children had fat measures equal to those of moderately and markedly overweight children. There were also some with larger fat measures. This occurred more frequently in girls than boys.

The difference in means of fat thickness, as indicated in figure 3 and table 6, shows an increase in mean fat thickness with the increase in weight status. For boys, the fat thickness was four times as great for the markedly overweight as for the average weight (10.8 mm. vs. 2.7 mm.). The comparison was approximately three times as great for girls (12.9 mm. vs. 4.4 mm.).

Comparison of the means of weight categories was made by the test of the significance using the F distribution in the analysis of variance after the fat distributions were normalized using McCall's technique, cited by Garn (21). The transformation to normalized T -score tended to normalize the fat distribution and provided equal variances. The F test showed a significant difference in means: Boys $F_{.01}(2,83)=4.9$, $F=36.8$; girls, $F_{.01}(2,80)=4.9$, $F=20.7$.

F tests permit an analysis which rejects the null hypothesis that all of the means are equal, but they do not provide a procedure for comparing specific means with one another. Multiple compari-

Table 6. Measurement of fat thickness of children by major weight category and by sex

Comparison	Confidence limits ¹	
	Male	Female
Average weight-overweight.....	13.8 ± 3.8	8.7 ± 4.3
Average weight-markedly overweight.....	-17.1 ± 4.8	-13.0 ± 4.8
Moderately overweight-markedly overweight.....	-6.5 ± 5.4	-8.6 ± 6.6
Average weight and moderately overweight-markedly overweight.....	-11.9 ± 4.6	-10.8 ± 4.6

¹ There is evidence, using the q statistic at the 5 percent level to reject the zero value for all the comparisons made, using the following formula: $\bar{X}_1 - \bar{X}_2 \pm \frac{\text{Student range}}{\sqrt{2}}$

$$\sqrt{\text{Mean square for error} \left(\frac{1}{n_1} + \frac{1}{n_2} \right)}$$

the mortality rate of 142 percent for all moderately overweight males.

It has been found from studies and reports from clinics for weight control that guided efforts toward their goals are ineffective and impermanent. It would appear that early onset of overweight is an important factor to consider when persons apply for treatment. Education and therapy should be directed toward weight control in the early stages of life. According to Young and others, overweight is "probably a continuing reflection of other childhood characteristics" (12).

Summary

A followup was made of children aged 10 through 13 years whose serial height-weights were recorded some 20 years ago to determine their present adult weight status.

It was observed that overweight children tend to become overweight adults more often than children of average weight.

The difficulty that obese adults experience in weight control may be rooted in the fact that overweight children tend to become overweight adults. It may, therefore, be reasonable to suggest that part of the failure of traditional weight control activities is due to overemphasis on adult eating patterns.

STATISTICAL NOTES

Validation of Relative Weight Measures

The term "overweight" is used interchangeably in this study with the term "obesity." Since overweight is defined in terms of departure of actual weight from a height-weight standard, no specific measure of fat is available. An effort was therefore made to validate the overweight measure, expressed

Figure 3. Distribution of fat thickness in weight categories, by sex, of children 10 to 13 years of age, Hagerstown, Md., 1937-39

of the distribution of relative weight. However, it should be stated that, on an individual basis, some of the overweight children, particularly the moderately overweight, could be classified as overweight not due to fat but due to frame or muscular development.

Bias From Followup Attrition

Locating and interviewing children originally examined in 1937-39 for a prospective study raised the question of how many of the selected study group could be found in 1958. Losses might introduce a bias as the weight status of the average and overweight individuals located and interviewed might not be representative of the average and overweight categories as initially selected. Tables 8 and 9 show the number of average weight and overweight males and females who were either available for interview or not available for interview in the original study selection, and the replacements made for those who were not available.

Bias is minimized in the average weight group because of the method used in selecting individuals for this category. The range of weights was plus or minus 5 percent about the relative weight of 100. This narrow range tended to decrease the difference between the weight status of those individuals interviewed and those individuals not interviewed. The difference between means was statistically not significant. For males of average weight, the mean relative weight of individuals not interviewed was 100.0 and of subjects was 99.7 ($.2 > P > .1$). For females of average weight, the contrast in mean relative weights was 99.9 as compared to 99.8 ($P > .9$).

The problem of attrition is more pertinent in the overweight than in the average weight category, since the range of relative weight selected from the distribution of relative weights of the total population varied from the relative weight of 180 to 116 for males and from 200 to 124 for females. The hypothesis that there is no significant difference between the distribution of relative weight of those persons who were interviewed and those who were not interviewed was tested by using the chi-square statistic. This test indicated that the difference between the groups could have arisen by chance ($.7 > P > .5$) and ($.8 > P > .7$).

son tests provide this method (22). Table 7 shows the statistical evaluation of these comparisons.

It is evident that there is a significant difference in fat thickness between average weight and overweight children, between a combination of average and moderately overweight with markedly over-

weight, between moderately and markedly overweight, and between average and markedly overweight children. These findings indicate that the markedly overweight children had, on the average, a larger measure of fat thickness than those selected from the remainder of the designated area

Health Manpower, 1930-75

WILLIAM H. STEWART, M.D., and MARYLAND Y. PENNELL, M.Sc.

HEALTH manpower is a matter of increasing concern to the United States in view of the rapid rate of growth of the population. The number of persons in the 48 States and the District of Columbia in mid-1959 is estimated at 177,128,000; by 1975 it is predicted to be 235,246,000, an increase of 33 percent. Whether an adequate supply of physicians, dentists, nurses, and other health personnel can be provided for the future depends on immediate planning for increased numbers of graduates in the health professions within the next few years.

Current Physician (M.D.) Supply

With an estimated 235,000 physicians in mid-1959, excluding the graduates of that year, the ratio of physicians to population now is 132.7 per 100,000 persons. Over the past 30 years the ratio has ranged between 125 and 135.

The latest count of the number of physicians in the 1958 American Medical Directory (1) indicated that there were 226,625 physicians in the 48 States and the District of Columbia in mid-1957. This number of physicians includes all those in the Federal Government service regardless of their actual location. The ratio is 132.4 per 100,000 total population including the Armed Forces overseas.

In Alaska in mid-1957 there were 101 non-Federal physicians or 62 per 100,000 civilians; in Hawaii, 574 physicians or 104 per 100,000 civilians. Outlying areas had even relatively fewer physicians (excluding those in Federal Government service).

Dr. Stewart serves as chief and Mrs. Pennell is a statistician of the Division of Public Health Methods, Public Health Service.

Area	Number of non-Federal physicians	Physicians per 100,000 civilians
American Samoa-----	3	15
Canal Zone (and the Republic of Panama)-----	187	19
Caroline Islands-----	5	12
Guam-----	17	40
Marshall Islands-----	1	13
Marshall Islands-----	2	14
Puerto Rico-----	931	41
Virgin Islands-----	24	92

Physicians range in age from under 25 years to 90 and older. Among the 226,625 in the United States in mid-1957, about 800 were younger than age 25. At the other end of the scale were about 30,000 physicians aged 65 and over, of whom only 8,000 were reported in the directory as retired or not in the practice of medicine. (An additional 3,000 younger physicians were also counted as retired or not in practice.)

The detailed age distribution of the physicians is given below:

Age group	Number	Percent
All ages-----	226,625	100.0
Under 30 years-----	23,235	10.3
30-34-----	34,163	15.1
35-39-----	31,185	13.8
40-44-----	28,635	12.6
45-49-----	27,219	12.0
50-54-----	21,815	9.6
55-59-----	16,817	7.4
60-64-----	13,021	5.7
65-69-----	10,253	4.5
70-74-----	8,250	3.6
75-79-----	6,057	2.7
80 and over-----	5,388	2.4
Unknown-----	587	.3

NOTE: Age is as of the beginning of the year 1957, based on the year of birth shown on the individual physician punchcard supplied by the American Medical Association to the Public Health Service.

Of the physicians alive in 1957, about 86 percent may be expected to be still living in 1965 and about 68 percent, in 1975. This number of survivors at future dates is ascertained by applying the 1956 age-specific white male mortality rates to the number of physicians in each age group, on the assumption that physicians die at about the same rate as white males of similar age in the total population. The assumption is consistent with the number of deaths reported annually to the American Medical Association.

Deaths of physicians account for 3,500 to 4,000 annual losses to the profession. Each year about 7,400 to 7,800 newly licensed physicians—graduates from medical schools in the United States, Canada, and other foreign countries—are added to the profession. Thus the annual net gain in the number of physicians is about half the number of new licentiates.

The 85 medical schools in the United States graduated 6,895 physicians in the academic year 1958-59 (2). The average (median) age at graduation is now about 26 years, the same as prior to World War II (3, 4). After this war and the Korean conflict the postponed education of veterans resulted in an increase to 28 years for median age at graduation for the class of 1950. By 1954, the median had declined to 27 years, with a further decline to 26 years by 1956. The tabulation based on recent graduates listed in the 1958 American Medical Directory shows that the disparity between ages at graduation has likewise declined. The middle 50 percent of the graduates covered a span of 5.3 years in 1950 as contrasted with 2.3 years for those graduated in 1956.

About 12 percent of the new additions to the profession in this country since 1950 were educated outside the United States. Of the physicians licensed to practice for the first time in this country in 1958, nearly 150 were graduates of Canadian schools and 1,166 were graduates of other foreign schools. The foreign school graduates include an estimated 400 American citizens who had gone to other countries for their medical education. A tabulation of recent licentiates graduated from Canadian and other foreign schools indicates that they are older, as a group, than those who enter the profession directly after graduation from U.S. medical

Trend in health manpower

schools. The median ages of the Canadian and other foreign school graduates are 30 and 36 years, respectively, when they obtain their first license to practice in the United States, as contrasted with age 26 for U.S. school graduates who are counted as entering the profession upon graduation rather than licensing.

Future Supply of Physicians (M.D.)

The future supply of physicians in the United States depends on (a) the current numbers now in the profession and their mortality, (b) the graduating classes of medical schools in this country, and (c) additions to the profession from Canadian and other foreign medical schools.

Of the 226,625 physicians (M.D.) in the United States in mid-1957, about 195,000 may be expected to be still alive in 1965. Between 1957 and 1965 the annual number of graduates of U.S. medical schools is planned to increase from about 6,800 to as many as 7,400. This reflects the development of new schools and expanded enrollment in existing schools, according to the American Association of Medical Colleges. During the same period the annual number of new licentiates graduated from Ca-

¹ For 1957, number shown in American Medical Directory 1958, table 1. For future years, numbers computed by method outlined in "Physicians in the United States: Projections 1955-1975," by G. St.J. Perrott and Maryland Y. Pennell. J. M. Educ. 33: 638, September 1958.

² Rates based on total population of the United States, including Armed Forces overseas, as of July 1; U.S. Bureau of the Census, Current Population Reports, Population Estimates, Series P-25, No. 187, Nov. 10, 1958 (p. 16, Series II). Thousands of persons: 171,196 in 1957; 180,126 in 1960; 195,747 in 1965; 213,810 in 1970; 235,246 in 1975.

³ Figures for 1957 and 1958 published in J.A.M.A. (Education Number) 168: 1503, Nov. 15, 1958; preliminary number for 1959. Figures for 1960-64 estimated by Public Health Service on basis of current enrollments. Figure for 1965 furnished by American Medical Association to House of Representatives Committee on Interstate and Foreign Commerce (85th Cong., 1st sess.); see Medical School Inquiry, p. 243. Figures for 1966-75 estimated by Public Health Service.

⁴ New licentiates graduated from foreign schools: 1,014 in 1957 and 1,166 in 1958; J.A.M.A. (State Board Number) 170: 603, May 30, 1959. Licentiates of Canadian schools not reported by A.M.A. estimated as 150 per year. Figures for 1959-75 estimated by Public Health Service.

⁵ Deaths computed on basis of 1956 age-specific white male mortality; National Office of Vital Statistics, Special Reports 6: 48, June 19, 1958 (table 2). Age distributions of physicians in 1957 of recent graduates of American medical schools and of recent licentiates graduated from Canadian and foreign medical schools were obtained from individual physician punchcards supplied to Public Health Service by American Medical Association.

nadian and other foreign medical schools may decrease. A conservative estimate for the year 1965 is 750, of whom 100 to 150 are graduates of Canadian schools and the balance are graduates of other foreign schools.

As shown in table 1, the number of physicians is expected to be nearly 260,000 in 1965, with a ratio of 132.8 physicians per 100,000 population (5). This 1965 ratio is almost the same as that of 1957 but shows a decline from the 134.9 level of 1949.

From 1965 to 1975, the annual number of graduates of U.S. medical schools may continue at the level of about 7,400 in accordance with the currently planned output of these schools. These graduates may be supplemented by an average of 750 graduates of Canadian and other foreign schools newly licensed each year. After death has taken its toll from both those already in the profession and the new additions, the number of physicians is expected to be about 279,000 in 1970 and 296,000 in 1975. The physician-population ratio will decline from the 1965 level of 132.8 physicians per 100,000 population to 130.5 in 1970 and still further to 125.9 in 1975.

If it is assumed that the ratio of physicians to population which prevailed in 1957 is the appropriate goal for 1975, there will be need for 311,500 physicians, instead of the 296,100 expected on the basis of the level of U.S. school output currently in sight. To obtain this total will require about 10,360 graduates of U.S. medical schools in the year 1975. This number of graduates is nearly 3,000 above the number now expected under current plans. Such an increase will have to be met through the expansion of existing schools and the construction of about 25 new schools, some with 2-year and some with 4-year programs.

Physicians (D.O.)

In 1930, the United States had approximately 10,300 doctors of osteopathy. By 1959 the number had increased to 14,100, giving a ratio of 8.0 per 100,000 population (table 2).

The six schools of osteopathic medicine graduated 469 physicians (D.O.) in 1959 (6,7). Currently planned enrollments indicate that by 1965 the annual graduating class may be increased to about 525.

If the output of these schools continues at the same level during the following decade, the supply of osteopathic physicians is expected to reach 16,700 by 1975, with the ratio declining to 7.1 doctors per 100,000 persons.

Dentists

Increases in dentist supply have been lagging behind population growth for more than a generation. From fewer than 75,000 dentists in 1930, the total supply in the 48 States and the District of Columbia has grown to almost 100,000 at the present time. Yet there are now only 56 dentists per 100,000 persons as compared with a ratio of 59 in 1930.

The dentist totals (table 2) include those in the Federal Government service and those retired or not in practice, but exclude graduates of the years concerned (8). While nearly all of the dentists of 1930 were of working age and active in the profession, today's dentist supply includes a large proportion who are inactive. As a result, the number of active dentists in relation to population has fallen even more steeply, dropping to only 49 per 100,000 persons in 1959, according to estimates prepared by the Public Health Service, Division of Dental Resources.

In mid-1957, one-quarter of the dentists were 60 years of age or older (9), as shown below:

Age group	Number Percent	
	All ages-----	97, 610 100. 0
Under 30 years-----	7, 492	7. 7
30-34 -----	12, 539	12. 8
35-39 -----	13, 137	13. 4
40-44 -----	9, 752	10. 0
45-49 -----	9, 249	9. 5
50-54 -----	10, 556	10. 8
55-59 -----	10, 355	10. 6
60-64 -----	9, 651	9. 9
65-69 -----	6, 233	6. 4
70-74 -----	3, 720	3. 8
75-79 -----	2, 714	2. 8
80 and over-----	2, 212	2. 3

Alaska had 47 non-Federal dentists, or 28 per 100,000 civilians in 1958. With 356 non-Federal dentists in Hawaii, the ratio was 62 per 100,000 civilians.

The U.S. dental schools number 47, having risen from 39 at the end of the war. In the

academic year 1957-58 they graduated 3,083 dentists (10). The median age at graduation is now about 26 years, having been 28 years in the period 1950-54 and 25 years prior to World War II (9).

Although the annual number of graduates is nearly 80 percent more than the number graduated 10 years earlier, this expansion has not produced enough new dentists to maintain the pre-war dentist-population ratio. Furthermore, at currently planned levels of school output the ratio of dentists to population will

continue its steady decline, as illustrated in the accompanying chart.

The annual number of graduates is expected to increase to nearly 3,500 by 1965. Unless there are further increases, however, the total number of dentists in the United States in 1975 will reach about 118,000. This number will be equivalent to only 50 dentists per 100,000 persons, of whom 46 will be active in the profession.

To regain the 1958 dentist-population ratio will require 133,250 dentists in 1975. An addi-

¹ Number of M.D.'s for 1957 from American Medical Directory, 1958; data for prior years based on earlier directories, projections by Public Health Service (see methodology in table 1).

² Number of D.O.'s for 1957 from A Statistical Study of the Osteopathic Profession, December 31, 1957, data for prior years based on survival of graduates of U.S. schools of osteopathy, projections by Public Health Service.

³ Number of D.D.S.'s for 1950-58 from Distribution of Dentists in the United States by State, Region, District and County (annual issues), adjusted to exclude graduates of years concerned, data for prior years based on survivals of graduates of U.S. dental schools, projections by Public Health Service.

⁴ Number of nurses for 1958 from Facts About Nursing, 1959 edition, 1957 figure is midpoint between 1956 and 1958 totals; data for prior years based on census enumerations, adjusted to exclude student nurses, projections by Public Health Service.

⁵ Rates for physicians and dentists based on total population including Armed Forces overseas since persons in Federal service outside the U.S. are included. Rates for nurses based on total population excluding Armed Forces overseas since nurses in Federal service outside the U.S. are excluded.

tional 2,700 graduates will be needed that year above the 3,500 currently planned for existing schools. This means a 75 percent increase in training capacity.

Professional Nurses

The nurse-population ratio in the United States has increased almost fivefold since 1910, according to the Public Health Service's Division of Nursing Resources. The ratio now is 267 per 100,000 population, with an estimated 467,000 active professional nurses in the 48 States and the District of Columbia in mid-1959 (table 2). The total number of graduate professional nurses probably exceeds 800,000 including those who are inactive for any reason.

In Hawaii there were 1,681 active registered nurses, or 320 per 100,000 civilians in 1956 (11). Data for Alaska are not available.

The 1,145 schools of professional nursing enrolled about 113,000 students and graduated 30,410 nurses in the academic year 1957-58 (12). Admissions to these schools may increase markedly by the mid-sixties, with the annual number of graduations up to 37,000 by 1965 and still going higher.

The number of nurses in relation to population will increase in accordance with the currently planned output of nursing schools. The ratio is expected to be 284 nurses per 100,000 persons in 1970, with about 608,000 professional nurses in active practice.

Summary

The future supply of physicians is not expected to keep up with the greatly accelerated rate of growth of the population. The predictions take into account estimates of the graduates of medical schools in the United States, new licentiates graduated from Canadian and other foreign medical schools, and deaths among those in the profession.

The number of graduates of U.S. medical schools currently predicted for existing and planned schools is expected to increase from about 6,900 in 1959 to 7,400 in 1965. The number of physicians (M.D.) in the latter year will be about 260,000, or 132.8 per 100,000 population which is about the present ratio.

If the number of graduates of U.S. medical schools were to remain at about 7,400 per year between 1965 and 1975, while the foreign-educated physicians entering practice in this country leveled off at 750 per year, the number of physicians (M.D.) in 1975 would be increased to 296,000. The ratio, however, will decrease to 125.9 physicians per 100,000 persons. If the annual number of U.S. graduates were to be increased sufficiently to maintain the present physician-population ratio in 1975, the 1975 graduating class would have to be increased to approximately 10,360, in order to have 311,500 physicians (M.D.) in that year.

The number of osteopathic physicians is about 14,000, with 469 graduates in 1959. If the annual graduating class is increased to about 525, by 1975 the supply of physicians (D.O.) may reach 16,700. The ratio to population will have declined, however, from 8.0 to 7.1 doctors per 100,000 population.

Increases in dentist supply have been lagging behind the population growth despite large gains in the numbers being graduated. The annual number of graduates is expected to increase from the present 3,100 to nearly 3,500 by 1965. Unless there are further increases, the number of dentists in 1975 will be about 118,000, or 50 per 100,000 population. To regain the 1958 ratio of 56 dentists per 100,000 population requires 133,000 dentists in 1975 and an additional 2,700 graduates that year above the number currently planned.

The supply of professional nurses has more than kept pace with the population growth. With 467,000 nurses now active, the ratio is 267 per 100,000 persons. The annual number of graduates is expected to increase from 30,400 in 1958 to 37,000 in 1965 and continue upward. On this basis, the ratio is expected to be 284 active professional nurses per 100,000 population in 1970.

films

A Survey of Refuse Disposal Methods

16-mm. filmograph, color, sound, 358 feet, 10 minutes, 1959, cleared for television. (Order No. FG-328.)

Audience: Sanitarians and State and local officials responsible for refuse disposal facilities.

This filmograph demonstrates the advantages and disadvantages of all widely used methods of refuse disposal—ranging from open dumps, dumping in oceans and rivers, and backyard burning to metropolitan incineration and sanitary landfills.

The filmograph is available on short-term loan, in the United States only, from the Communicable Disease Center, Public Health Service, Post Office Box 185, Chamblee, Ga.

It can be purchased from United World Films, Inc., 1445 Park Ave., New York 29, N.Y.

The Membrane Filter

35-mm. filmstrip, color, sound, 80 frames, 12 minutes, 1959, not cleared for television. (Order No. F-386.)

Audience: Anyone who might be expected to use the filter techniques.

Designed to familiarize audiences with the use of the membrane filter, this filmstrip depicts its advantages

and disadvantages as compared with other methods of examining water, outlines the newest techniques and procedures, and shows the equipment required.

For short-term loan, in the United States only, the filmstrip is available from the Communicable Disease

Center, Public Health Service, Post Office Box 185, Chamblee, Ga. It can be purchased from United World Films, Inc., 1445 Park Ave., New York 29, N.Y.

Federal Publications

From Research to Classroom Laboratory, Part 2. A series of demonstrations on the science and engineering of man's environment for healthier living. *OM 1274; 1959; 52 pages.*

Eight experiments designed to bring an awareness of environmental health factors to high school students are reprinted from the *Science Teacher*.

Subjects investigated are fluoride contamination of food materials, additives in meat, taste and odor contaminants in drinking water, fluid metering, reducing evaporation of water by using hexadecanol, culturing bacteria on membrane filters, high-temperature, short-time pasteurization of milk, and determination of half-life.

Experiments given in part 1 are listed.

A Dental Society Reports on Budget Payment. A case study of the Kana-wha Valley Dental Society payment plan. *PHS Publication No. 717; 1959; 28 pages.*

Organization, operation, and first year's utilization of a budget payment plan in which patients finance dental care through special bank loans at nominal interest rates are described.

The dentists' reasons for joining the plan, effects they believed it would have on dentist-patient relationships and financial aspects of practice, and the plan's possible contribution to better oral health standards for the community are discussed in relation to utilization patterns.

Principles for Planning the Future Hospital System. A report of proceedings of four regional conferences. *PHS Publication No. 721; 1959; 234 pages; \$1.25.*

Regional conferences held in Chicago, New Orleans, Salt Lake City, and Washington, D.C., during April and May 1959 are recounted for groups or individuals concerned with hospital planning.

Divided into three parts, this report presents all the major speeches along with a condensation of each speech, a report from each of the 16 workshops and a summary of their activities, and a listing of registered participants.

The appendix contains background material used as a basis for discussion.

Patients in Mental Institutions, 1956. Part I. Public institutions for mental defectives and epileptics. Part II. Public hospitals for the mentally ill. Part III. Private hospitals for the mentally ill and general hospitals with psychiatric facilities. Part IV. Private institutions for mental defectives and epileptics. *PHS Publication No. 632; 1959; part I, 48 pages; part II, 72 pages; part III, 41 pages; part IV, 27 pages.*

Tabulations of basic statistical data on the movement of patient populations in mental institutions for each State and the United States are presented. The data were derived from the 30th annual census of patients in mental institutions.

Parts I and II contain detailed tables on first admissions and resident patient characteristics, on personnel, and on maintenance expenditures. Parts III and IV present characteristics of first admissions to private mental hospitals and private institutions for mental defectives. Part III also includes characteristics of patients discharged from psychiatric facilities of general hospitals. Scope and limitations of the data are discussed, and a section on definitions is included in each part.

Sources of Morbidity Data, Listing Number 7, 1959. *PHS Publication No. 716; 1959; 88 pages.*

Descriptions of 116 current morbidity statistics projects are grouped according to disease category or injury. Projects are indexed by type of data collection, organizations re-

sponsible for the research (by State), and principal investigators. Status of incompleting projects from previous listings is given in the section of supplementary notes.

The listings are published primarily for the use of research workers and persons planning public health programs. Tearsheets of the project descriptions are available for persons who inquire about studies of a particular type.

Proceedings, 1959 Annual Conference of the Surgeon General, Public Health Service, and the Chief, Children's Bureau, with State and Territorial Health Officers. *PHS Publication No. 722; 1960; 27 pages.*

Recommendations and actions of the Association of State and Territorial Health Officers are presented in separate sections for each of its standing and special committees and for the Long-Range Planning Subcommittee.

Committees cover Federal relations, environmental sanitation, hospitals and mental health, infectious diseases, long-term illness and health of the aging, maternal and child health, health and medical services, research, civil defense, Indian affairs, and migrant labor.

Resolutions adopted by the Association of State and Territorial Health Officers are also presented. Officers and executive committee members of the association are listed for 1958-59 and 1959-60.

This section carries announcements of new publications prepared by the Public Health Service and of selected publications prepared with Federal support.

Unless otherwise indicated, publications for which prices are quoted are for sale by the Superintendent of Documents, U.S. Government Printing Office, Washington 25, D.C. Orders should be accompanied by cash, check, or money order and should fully identify the publication. Public Health Service publications which do not carry price quotations, as well as single sample copies of those for which prices are shown, can be obtained without charge from the Public Inquiries Branch, Office of Information, Public Health Service, Washington 25, D.C.

The Public Health Service does not supply publications other than its own.

THE NATIONAL HEALTH SURVEY*

SCOPE AND METHOD OF THE NATION-WIDE CANVASS OF SICKNESS IN RELATION TO ITS SOCIAL AND ECONOMIC SETTING

By GEORGE ST. J. PERROTT, *Principal Statistician*, CLARK TIBBITTS, *Field Director*,
and ROLLO H. BRITTEN, *Senior Statistician*, *United States Public Health Service*

During the winter of 1935-36 the United States Public Health Service inquired into the state of the Nation's health and underlying social and economic factors by means of a house-to-house canvass of over 700,000 households in urban communities in 18 States¹ and 37,000 households in rural areas in 3 States. The present paper sets forth the purpose and scope of the survey, outlines in some detail the method of sampling and canvassing, compares various aspects of the population with 1930 Census data as a rough measure of the reliability of the Health Survey sample, and records the major definitions employed in the survey. Subsequent papers to be published in the *PUBLIC HEALTH REPORTS* or as special monographs will present the detailed findings.

SCOPE OF THE SURVEY

The data necessary for comprehensive analysis of national health problems are not available from regularly compiled records. Local, State, and Federal health agencies collect information principally on births, deaths, and a limited list of incompletely reported communicable diseases. On the frequency of accidents and disabilities resulting therefrom, only approximate estimates based on records of insurance companies, workmen's compensation commissions, and industrial and safety organizations have been available. As to the provision of medical care, records of doctors, hospitals, and health agencies lack the uniformity and centralization necessary for statistical comparisons. Any adequate picture of care received in relation to needs can be obtained only through family reporting.

SEPTEMBER 15, 1939, pp. 1663-1687

The goal and scope of the 1935-36 National Health Survey of the Public Health Service were defined by George St. J. Perrott, Clark Tibbitts, and Rollo H. Britten in this article which also outlined survey methods and techniques.

Nursing home aides were trained in pilot study in Oklahoma to find answers to questions on course standards, staffing, and administration and to observe corollary improvements in patient care.

Training Nursing Home Aides

GENEVIEVE R. SOLLER, R.N., B.S., M.P.H.

FEW TASKS are more perplexing for the public health worker than those concerned with improving the care of the patient in the nursing home. The average patient is old and has a long-term disease or a disability, which may be exaggerated or complicated by existing socioeconomic, emotional, and spiritual problems. Meeting the needs of the patient requires not only special knowledge and skills to cope with his medical condition but also the ability to understand and deal with his personal problems.

Essentially, the primary service given in the nursing home is nursing care. This may range from the nurturing, protective type to the more complex and comprehensive; from tasks requiring know-how easily gained through observation or training on the job to those acquired only through extensive technical training and professional education.

A substantial number of nursing home patients are receiving nursing care that is not of professional quality or planned to meet individual needs. Most frequently the care is given by untrained, unskilled nursing aides who find themselves called upon to perform tasks requiring skills, knowledge, and judgment beyond their competencies. More often than not, the

"nursur" of the patient is functioning without benefit of qualified nurse supervision or procedure manuals.

For special training of nursing home personnel, the Public Health Service developed the manual "How to be a Nursing Aide in a Nursing Home." The manual contains selected nursing procedures to be taught to nursing aides and adapted by nursing homes to standardize practices and maintain a higher quality of care. The Public Health Service also allocated funds for a pilot study in a single State to test the manual, train aides, and note observable changes, if any, in patient care. It was recommended that the study method be simple and easily duplicated by another State. The study was expected to yield significant information useful to the State in planning and strengthening its nursing home program.

Oklahoma was selected for the study, conducted from January 1 to December 31, 1958, because the Oklahoma State Department of Health is responsible for licensing nursing homes; the problems related to nursing home care were likely to be similar to those in other States; and the State had had previous experience in training nursing aides for hospital service. In line with the purposes stated above, the study sought to demonstrate how patient care can be improved in nursing homes through planned instruction of nursing aides using the content of the manual and the rapid training method of teaching (1), and to find answers to questions relating to course admin-

Mrs. Soller serves as assistant chief nurse of the Chronic Disease Branch, Public Health Service. The paper is based on a report of the study prepared by Norma C. Schaefer, Oklahoma State Department of Health, and Mrs. Soller.

istration, staffing, teacher and trainee-aide recruitment, and training costs.

This paper recapitulates the highlights of the study project method, findings, and recommendations.

Method of Study

The pilot study was organized and administered by the division of public health nursing, Oklahoma State Department of Health, with other divisions cooperating to assure integration with the total program of the health department. Consultation, assistance with data analysis, and preparation of the final report were provided by the Public Health Service's Chronic Disease Branch (fig. 1).

The central office staff consisted of a full-time coordinator, a qualified nurse consultant familiar with the rapid training method of teaching, and a part-time secretary. The coordinator's function was to select and train teachers for the courses; promote, coordinate, evaluate the study; and collect data.

State and local advisory committees were appointed to give support and assistance to the current study and possible future training programs. The limited membership was representative of public and private agencies, institutions, or groups interested in or giving services to nursing home patients. Local health department nursing personnel assisted with community organization, public education, and teacher recruitment. One of the purposes of the study was to determine whether graduate professional or licensed practical nurses living in the local area could be recruited to give aide training. The teachers were to be employed on an hourly basis to organize the courses, teach the aides, and supervise their practice in the nursing home as well as collect data.

The collection of data was a continuous activity and the responsibility of the teachers and the coordinator. Application blanks, evaluation forms, teacher observational visits to nursing homes, classroom and anecdotal records, narrative reports, and terminal conferences were used to gather information for use in the study and for planning future programs.

The study group, consisting of 71 nursing homes taken from the 1957 licensed nursing

home population, included 4 types of geographic areas: metropolitan, cluster, scatter, and rural.

Of the 291 nursing aides employed in the nursing homes, 211 were nominated for training by operators of these homes. The teachers made the final selection of trainee-aides on the basis of their ability to read and write; whether they actually were giving patient care; and their willingness to complete the course.

Teacher Training

The study coordinator conducted a 3-day workshop for the teachers. They were acquainted with the study purposes, policies, procedures, training methods, forms for collecting data, and the relationship of the study to the objectives and procedures of the State health department's nursing home program. A visit was made to a nursing home for orientation to the nursing environment, types and characteristics of the patients, and the teachers' role and functions. In addition to the workshop, teachers attended two conferences: the first, at the midway period of the pilot study and the second, at the end. The first conference provided an opportunity for progress reports, exchange of ideas and experiences, and discussion of problems and possible solutions. The second was held to assess the total project and to receive recommendations for improving the course and for revising forms used to collect data.

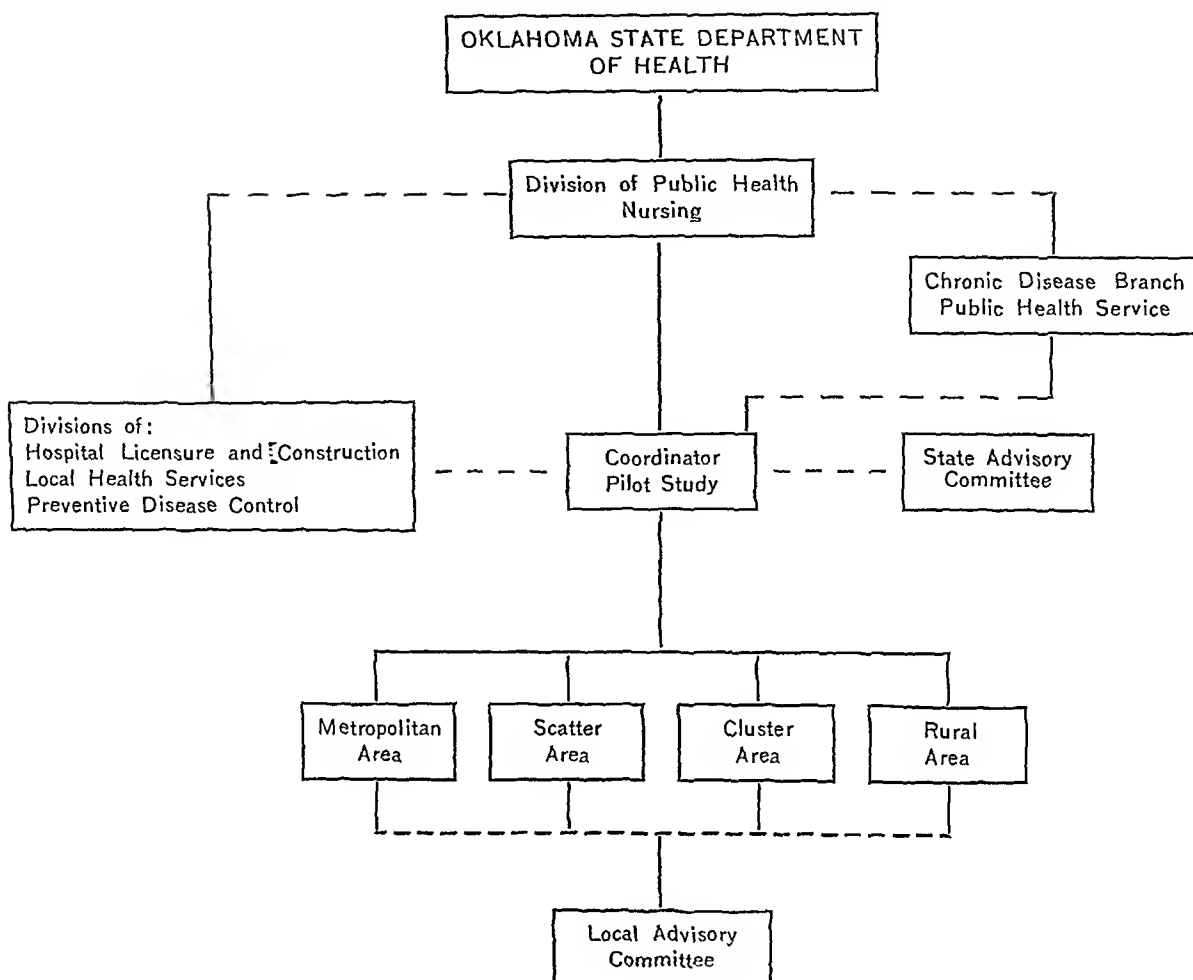

Prior to organizing a course, the teacher visited each of the nursing homes from which aides were to be trained to familiarize herself with the work environment and prepare for limited supervised practice for the trainee. At the same time, she informed the operator of the nursing home of the plan for a followup visit to the home 3 months after completion of training to observe the job performance of the aide.

Courses for the aides were conducted in temporary training centers located and equipped either by the local advisory committee, teacher, health department, or community, or a combination of these.

Development of Course Content

There was no pattern for the teacher to follow in the development of the course. Each

Figure 1. Organizational chart of the pilot study

teacher experimented with the number of class hours required to teach the content and to supervise practice. The class size was limited to not less than 6 and no more than 10 trainees.

The training manual provided the primary content for the course, but the sequence of the units and the selection of procedures to be taught were left to the judgment of the teacher.

To help the teacher determine the nature of the training needed by the aides, the operators of the selected nursing homes were asked to classify patients by judging their nursing needs. Teachers also attempted an inventory of tasks that trainee-aides performed to determine what competencies should be expected of the aides and what preparation would be needed to meet their job requirements. On the basis of observations in the nursing home, pa-

tient classification, and the inventory, the teacher developed the course content. It is worth noting that some of the tasks that the aides professed to be performing were highly technical and, according to the recent function studies of the American Nurses' Association, would require the knowledge and skill of a professional nurse.

Findings

Of the 71 homes participating in the study, approximately 20 percent had been in operation less than a year. Most of them had less than 20 beds with an estimated 83 percent occupancy. It was estimated that 81 percent of the patients were on some form of public assistance.

As perceived by the operators, approximately

two-thirds of the patients required complete bed care and about one-third some nursing care. The small number remaining were considered capable of self-care (fig. 2). The department of public welfare pays more for the patient on bed care than self-care, which may have influenced the classification.

The operators of the homes had a variety of background experiences. By far the largest number (49 percent) were housewives; the next largest group (42 percent) had some business experience. Thirteen percent listed themselves as licensed practical nurses by waiver and not by education. The situation calls for concern because not a single graduate nurse was among the operators or employees in the homes. Although no operator reported preparation for administering a nursing home, it must be recognized that no educational institution within the State offers a course in nursing home administration. The operators assume responsibility for the management of the home, judge the patients' nursing needs, plan patient care, and assign tasks for the aides to perform or do the jobs themselves.

Turnover in nursing aide staff was high in all nursing homes in the study group. In the scat-

Figure 2. Percentage distribution of patients in 71 nursing homes according to nursing care classifications, by geographic areas

Definitions

Geographic area classifications referred to in the study were defined as follows:

Metropolitan: a city-county under supervision of the health department with nursing homes of all sizes located in the city and county.

Cluster: an area under supervision of the local health department with nursing homes of all sizes located in one town.

Scatter: an area under the supervision of the local health department with homes of all sizes located in several towns.

Rural: an area with nursing homes, which may or may not have a local health department.

ter area approximately 75 percent had been in their jobs less than 1 year as compared with 65 percent in the cluster area, 49 percent in the metropolitan area, and 43 percent in the rural area. No attempt was made to determine the causes of the high rate of aide mobility. However, one teacher reported: "In one home the aides work 10 hours a day, 7 days a week, and are docked from their check if they take a day off. There are no paid vacations. As a result they are changing employees frequently." Other teachers told of "raider" practices among the homes. Nursing aides sometimes "raid" the employer's nursing home of patients, resign, and open their own facility. Standards of practice and the quality of patient care were most likely affected by the frequent change in staff personnel.

The age range of the 211 trainees was 21 to 75 years, with the median age 45 years. The majority were married and maintained homes in addition to service for hire. The level of education ranged from fourth grade through college. Figure 3 presents a graphic picture of this distribution based on 204 responses to questionnaires on education and background: 44 percent completed seventh grade or less; 38 percent completed eighth grade; 16 percent finished high school; and 2 percent, college. These persons give nursing care regardless of the degree of medical illness or level of nursing care required. Unfortunately the functions of nursing aides had not been defined by the State,

therefore no criteria were available to determine what they should or should not be doing. Prior to the study, no training facilities or courses were available to prepare the aide for the job.

Of the 211 nursing aides who enrolled, 184, or 87 percent, completed the course. Fifty-one were operators of nursing homes; however, for purposes of the study they were classified as aides. The largest number of "drop-outs" occurred during the latter part of the course. The teachers queried operators to determine the causes of "drop-outs" and concluded they were mainly: personal reasons, "knew it all," had previous training, fired, and other business employment.

The 24 training courses conducted ranged in length from 3.5 to 8.5 weeks. No definite number of hours was selected for teaching the procedures in the manual. Class periods lasted for 3 hours a day and were held twice a week. The actual hours of classroom teaching ranged from 21 to 51; the median was 34.5 hours. One teacher who had participated in the hospital aide training program thought 40 to 60 hours should be spent for the classroom teaching rather than the 30 hours she taught. Another

teacher, formerly on the staff in a school of practical nursing, thought 51 hours inadequate for training aides having the education level of her group. Supervised practice ranged from 8 to 20 hours. The time of day the teacher supervised practice varied from 6:30 a.m. to 5:00 p.m. The total course hours, including classroom teaching and supervised practice, ranged from 31 to 60 hours; the mode was 40 to 49 hours.

Evaluation

Subjective evaluation of the training courses by aides, operators, and teachers was also part of the study. At the end of each course, each aide and operator had an opportunity to express her reactions anonymously through an unstructured opinionnaire. The teachers made an overall evaluation, at the end of the study, of their own orientation, teaching methods, supervision of practice in the home, content of the course, and changes in the nursing care of patients and the behavior of the nursing aides.

About 80 percent of the aides considered the course helpful, useful, important, interesting, or a good review. More than 60 percent reported that they learned new skills and the

Figure 3. Educational level of 204 nursing aides in the pilot study

two-thirds of the patients required complete bed care and about one-third some nursing care. The small number remaining were considered capable of self-care (fig. 2). The department of public welfare pays more for the patient on bed care than self-care, which may have influenced the classification.

The operators of the homes had a variety of background experiences. By far the largest number (49 percent) were housewives; the next largest group (42 percent) had some business experience. Thirteen percent listed themselves as licensed practical nurses by waiver and not by education. The situation calls for concern because not a single graduate nurse was among the operators or employees in the homes. Although no operator reported preparation for administering a nursing home, it must be recognized that no educational institution within the State offers a course in nursing home administration. The operators assume responsibility for the management of the home, judge the patients' nursing needs, plan patient care, and assign tasks for the aides to perform or do the jobs themselves.

Turnover in nursing aide staff was high in all nursing homes in the study group. In the scat-

ter area approximately 75 percent had been in their jobs less than 1 year as compared with 65 percent in the cluster area, 49 percent in the metropolitan area, and 43 percent in the rural area. No attempt was made to determine the causes of the high rate of aide mobility. However, one teacher reported: "In one home the aides work 10 hours a day, 7 days a week, and are docked from their check if they take a day off. There are no paid vacations. As a result they are changing employees frequently." Other teachers told of "raider" practices among the homes. Nursing aides sometimes "raid" the employer's nursing home of patients, resign, and open their own facility. Standards of practice and the quality of patient care were most likely affected by the frequent change in staff personnel.

The age range of the 211 trainees was 21 to 75 years, with the median age 45 years. The majority were married and maintained homes in addition to service for hire. The level of education ranged from fourth grade through college. Figure 3 presents a graphic picture of this distribution based on 204 responses to questionnaires on education and background: 44 percent completed seventh grade or less; 38 percent completed eighth grade; 16 percent finished high school; and 2 percent, college. These persons give nursing care regardless of the degree of medical illness or level of nursing care required. Unfortunately the functions of nursing aides had not been defined by the State,

of equipment and supplies, lack of standards of nursing care, and lack of qualified nurse supervision. Inadequate staffing and frequent changes in staff affected the time she had to carry out procedures accurately and skillfully. Frequently the assigned tasks were beyond her abilities; sometimes the duties were in a different area, such as laundry work and housekeeping.

Of the teachers, 57 percent pointed out the need for improved personnel policies and better salaries for nursing aides. One teacher suggested that the doctors be informed of what the aide has been taught to do and her limitations, thus providing him with criteria for the selection of patients and referral to nursing homes.

Observable Effects

Though no tests or objective measurements of change in patient care were made before or after the nursing aides were trained, there was evidence of changes or improvement in patient care. In observing the practices of the aides before and after training, the teacher-trainers concluded that patient care had improved in most of the nursing homes. Nursing home administrators concurred in this conclusion as did the public health nurses who evaluate the homes for the State licensure agency. While these reports were all subjective in that each person was free to use her own criteria for evaluation, the agreement is noteworthy, and we believe, indicative of real improvement in care.

One of the most striking indications of improvement was in the personal appearance of patients as a result of better general nursing care. There was improvement in the techniques of bathing, feeding, and toileting. More patients were out of bed, and social activities were instituted to bolster their outlook on life. Odors decreased noticeably; patient units were cleaner and more functional; and soiled linen was no longer thrown on the floor but placed in a new or improvised hamper.

The pilot study provided for a followup visit to the aide in the nursing home 3 months after completion of training to observe the job performance. Approximately one-half of the teachers made these visits before the termina-

tion of the study. The number of aides in each geographic area who completed the course and the number remaining in the nursing homes at the time of the followup visit are as follows:

Area	Completing course	Followup
Metropolitan -----	57	44
Scatter -----	24	18
Cluster -----	17	14
Rural -----	23	16
Total -----	121	92

Although 121 aides had been trained, only 92 were still employed in the same nursing home; an attrition of 24 percent. The reasons, as stated by operators, are given according to order of frequency: personal reasons, entered practical nurse school, fired, employed in another home, other type of work, and working in hospital.

Problems Encountered

The study was not without its problems. Locating the training centers was difficult and required a great deal of teacher and public health nurse time for visits and telephone contacts. Since no classroom was permanent, it was necessary to obtain equipment on a temporary basis from hospitals, health centers, and nursing homes. Sometimes equipment had to be returned at the end of the class and brought back for the next session.

Although it was agreed that classes should be held on duty time, the aides from all homes with the exception of one, had to attend in the evening after a day of work. Frequently they were tardy, and had not read the assignment, which slowed up class progress.

Supervised practice in the home as a part of training had difficulties too. Most teachers were of the opinion that the actual hours made little difference for if the home was notified in advance, the work was done before they arrived and the purpose of supervised practice in the home was negated. It proved advantageous to go on unscheduled visits to learn how procedures were carried out. The following is offered as evidence: "One home did not use draw sheets on incontinent patients' beds except the day I was to supervise."

fundamentals of general nursing care needed to carry out their job responsibilities. In addition to better working methods, the aides learned work planning and organization, self-protection, and ways of working with others. The operators reviewed the course in terms of improvement in patient care. Fourteen percent observed new or improved techniques; 4 percent, better work organization; and more than 15 percent, interest in the patient as a person. One operator remarked that the training stimulated older workers and improved relationships among aide personnel and between aide and patient. Some commented that the aides seemed happier in their work.

Although the majority of responses were favorable, the negative reactions of 12 nursing aides (or 7 percent) merit serious consideration. They thought the content of the course was too elementary and that it did not equip them to perform the tasks required in the nursing home, such as giving "shots" and catheterizations, administering medicines, and treatments and measuring blood pressure. Likewise, 25 operators, or 45 percent, were dissatisfied with the course because it was too basic for experienced aides: they needed instructions in such things as "shots," first aid, rectal feedings, catheterizations, blood pressure, and medications.

The Teachers' Reactions

Although each teacher was required to attend an orientation course (workshop) prior to conducting aide training classes, many teachers later found themselves confronted with multiple and complex problems unrelated to course content and beyond the scope of the study. The 3-day workshops proved adequate for learning the rapid method of training, fundamental in using the aide manual. But the teachers expressed a need for additional information about the State nursing home program and the nursing home law. They felt their functions should be more clearly delineated and interpreted to nursing home operators. They found teaching and supervision in the home complicated by the operators' request for help with administrative decisions within the home; by the operators' lack of understanding of the rules and regulations as they relate to

standards of nursing care; and by the operators' lack of knowledge of nursing care.

There was need for more assistance in ways and means of improving practice in the nursing home where qualified nursing supervision was lacking and in methods of working with operators who lacked the knowledge necessary to teach and supervise aides. All teachers found it difficult to adhere to their job functions as they understood them and to avoid involvement in nursing home and licensure agency problems.

The teachers felt that their ability to teach and the aides' ability to learn was influenced by a number of factors. The training center, itself, affected the learning situation. It was frequently a long distance from the nursing home, crowded, poorly ventilated, and difficult to reach because of stairs. Very early teachers became aware of the great disparity in education and experience of each class group. The level of preparation influenced the amount of discussion that took place and the speed with which the procedures were mastered. It was sometimes necessary to hold the group back for the slower ones to catch up. The lack of reading ability and comprehension was sometimes embarrassing to the learner. Mixed groups (much and little education and experience) did not prove to be a handicap in all classes or with all teachers. The aides who were quicker to learn tended to help the slower ones.

Fifty-seven percent of the teachers observed a very high fatigue element among the trainees. However, fatigue, limited education, or difference in experience did not dampen the aides' enthusiasm or eagerness to learn. Each aide seemed grateful for the opportunity and took pride in self-improvement. The groups from the beginning to the end maintained a remarkable esprit de corps.

The nursing home situation frequently influenced the aide's ability to practice what she had learned. Among these was the attitude of the operator. In the homes where operators enrolled in the class as trainees, there was a receptiveness to change. In homes where the operators did not attend the class, sometimes there was objection to change: "That is not the way we do it here!"

Teachers found that the aide was often handicapped in performing her duties because of lack

Not one mother has left the hospital against medical advice since homemaker services were provided in a Texas county.

Hidalgo County Homemaker Program

HOWARD JUSTISS

HIDALGO COUNTY'S public welfare agency in its child welfare work has the distinction of being the first to provide homemaker services in Texas. We feel these services

answer a vital need in our county. Actually, there are some parts of our homemaker service which we do not like but cannot change immediately because of our financial situation. I want to tell you about some of the weak points as well as the strong; the good and the bad.

Imagine yourself in the southernmost city of Texas, Brownsville at the mouth of the Rio Grande. Travel up the river about 75 miles, turn directly north, and go another 20 miles. You will find yourself in Edinburg, the county seat of Hidalgo County. There are about 16,000 people in Edinburg when all the migrant workers have returned from the north, which usually happens in December. There are about 200,000 people in Hidalgo County. It is a large county and much more thickly populated than some counties I know of in Texas. The chamber of commerce would prefer that I tell you only the attractive things about the region, such as the good, tree-ripened citrus fruits, the beautiful palm trees, the many oil and gas wells, the fine cattle, and the warm winter vacationland;

Mr. Justiss is regional service supervisor, State Department of Public Welfare, Hidalgo County Child Welfare Unit, Edinburg, Tex. This paper was delivered at the Round Table Conference on Homemaker Service of the American Public Welfare Association in Washington, D.C., December 4, 1959.

but I feel that you should know more than these facts because there are some which influence our child welfare homemaker program.

We have a population of 75,000 children, many of them from large families whose parents are poorly paid farm laborers. Wages are from \$4 to \$5 per day when they work.

Because of inadequate diet, lack of medical care, overwork, and poor health standards, incidence of tuberculosis is extremely high. In the South Texas State Tuberculosis Hospital, located in the adjoining county, there were 473 patients on August 31, 1959. Of that number 205, or 43 percent, were from Hidalgo County.

There are great social and cultural differences. Seventy percent of the residents are Latin-American, or Spanish-speaking; others are those who have settled there from the colder regions "up north."

Our child welfare agency is charged with the responsibility of providing protective services to children who are "dependent" and "neglected," as defined by our State laws. This includes the usual provisions for foster-home boarding care, casework services, and adoptions. Homemaker service came to be a part of our program as a result of an experiment with two family situations. I would like to tell you briefly about these two families before we discuss other features of the work.

On a visit to the home of Mr. G in Edinburg, Tex., we might see a family of two girls and three boys getting ready for school. We would be in a small frame house with two bedrooms, a kitchen, and an outdoor toilet. It is a very modest house, but what you would

One purpose of the pilot study was to determine the availability of graduate professional and trained practical nurses in the four geographic areas to teach classes on a part-time basis. Professional nurse recruitment was difficult because of the paucity and lack of interest in teaching on the part of those available. Another aim was to experiment with trained practical nurses as teachers of the course. Their recruitment was an even greater problem, and it was not until the last quarter of the study that one was available.

The study also supplied an estimate of the cost of training each aide. The estimates were based on salaries, travel expenses, and per diem fees of teachers and coordinator, and supplies, but did not include rent, utilities, laundry, and similar items. Roughly the cost was approximately \$416.67 for each class, or \$54.35 for each nursing aide trained.

Discussion

The pilot study included only 16 percent of the 454 licensed homes in the 1957 Oklahoma State Inventory, leaving 383, or 84 percent, presumably in need of training assistance. Since the 184 nursing aides trained were recruited only from nursing homes, the course was a type of inservice training. No consideration was given to preservice training. Within the State there also are convalescent rest homes which, according to the State Advisory Committee, have patients requiring all levels of care and employ nursing aides. It may be assumed that nursing aides in all three types of homes could benefit from training which would be reflected in improved patient care.

The 1958 Oklahoma State Inventory of Homes (all types) showed a nursing staff of only 14 graduate registered nurses, 35 licensed practical nurses, and 1,200 nursing aides giving nursing care to patients. In the study sample of 71 homes no professional nurses were employed. Therefore, no one with professional competence was available to assess patient needs, assign tasks, or supervise nursing care.

There is no educational institution in Oklahoma where nursing home operators can obtain training in administration of a nursing home or nursing services, the primary therapy in the nursing home. Also, there are no qualification requirements (educational or physical) or definitions of functions for either the nursing home operator or the nursing aide. This means that ways of identifying what operators and nursing aides should or should not be doing are currently unavailable.

During the study teachers repeatedly called attention to the absence of supervision of nursing practice, lack of standards of nursing care, lack of procedure manuals, and the lack of equipment for the care of patients in nursing homes which affect the quality of nursing care. It was felt that both operators and aides could be helped considerably in job performance through special training. The high rate of turnover in nursing aide staffs emphasized the need for regular and continuous offering of such training.

It was recognized that the effectiveness of aide training programs depends to a great extent on some one person to provide the leadership and to coordinate the program's activities and interests of the community and participating groups. Adequate staff and sufficient time for teaching and followup are essential. In addition, there should be a definite source to provide financial support in the training programs.

It has been demonstrated that such training programs can contribute to improved patient care but that many related problems remain unsolved and require further study.

The manual, How To Be a Nursing Aide in a Nursing Home, by Dorothy E. Recsc, may be obtained from the American Nursing Home Association, 1346 Connecticut Avenue NW., Washington 6, D.C., at \$2.50 a copy.

makers to care for 48 families including 236 children. Most of these children would have required boarding care for long periods of time in foster homes had this arrangement not been available. I need not point out the advantages to each child of remaining in his own home, but another factor made sense to our commissioners—the homemaker services cost less than foster-home boarding care. Homemaker services for the G family for 5 years have cost the county about \$6,240. Foster care for these five children for the same length of time would have cost about \$12,000, and would have included no help for Mr. G himself.

We pay our homemakers \$20 to \$25 per week. Usually they are widows with no family responsibilities, neighbors to the family in distress, and acquainted with the children. They love children and accept willingly the household duties required in caring for them. Also they are familiar with financial deprivation and can manage well on limited incomes, inadequate housing, and few facilities. (One homemaker, who was required to live with a family of small children in a house with only one bedroom, slept on an Army cot in the lean-to kitchen every night for several months.)

And they are interesting people. For example, one lady is in this country on a passport. She was brought up on a ranch in Mexico, lived several years in Laredo, Tex., where her father was a merchant, and later became a professional dancer and actress in this country. She came to Texas from Mexico a few years ago to earn money for the care of her invalid husband. He was a professional bullfighter who was gored by a bull. He now lives with his mother in Monterrey, Mexico, while his wife works for us as a homemaker to support him. She is the "life of the group" at our regular meetings for in-service training.

One caseworker assumes responsibility for all families receiving homemaker services. For 2 years now, we have held regularly scheduled meetings of our caseworkers, to add to their training and insight in helping these families. We use our home demonstration agent, the chief county health nurse, and our own staff in teaching such subjects as general child care practices, recognition and care of childhood diseases, preparing balanced meals on low-income budget,

mending clothes and sewing, budgeting and buying both foods and clothing, and personnel policies.

We have used a total of 57 homemakers in 48 different family groups. The family situations which required homemaker services were:

- In 24, or 50 percent, the mother was hospitalized because of tuberculosis. In two of these homes, both parents were hospitalized at the same time, and the homemaker lived with the children on a 24 hours a day, 7 days a week, basis.

- In four homes, the mother was mentally ill. In most cases, she was hospitalized.

- In four homes, the mother had died. In one of these, the father had also passed away, so the homemaker lived with the children until permanent provision could be made for them.

- In four homes, the mother had cancer.

- In 12 homes, either there were other illnesses, the mother had abandoned the children, or other circumstances required the mother's absence for long periods of time.

The average length of stay of the homemaker to aid these 48 families has been 7 months.

Our homemaker program has certain unique features. Homemakers are selected usually from the immediate neighborhood or town where the family lives. In many instances, she is known to the children and is a friend of the parents. Hidalgo County is a large county, and even though the northern section is ranch country and sparsely settled, other sections, covered by small citrus groves, are thickly settled. There are 10 small towns or distinct communities with populations of from 3,000 to 30,000. Because many homemakers refuse to work in an adjoining community which may be 5, 10, 15, or 25 miles distant from their own homes, each homemaker is employed for the duration of a specific case. We have been able to persuade some, however, to take other cases, even if it meant travel.

Homemakers are not employed by the month or by the year or permanently, but for the duration of need in a particular family. The first one employed is in the same home after nearly 5 years; others remain 6 months to 1 year.

We do not use homemakers for very short periods, such as a brief hospital stay of a mother. I think we should, but it takes so long

expect for a rent of \$25 per month. The youngest child, a boy 6 years old, probably would be asking the 50-year-old lady in the house, whom he calls "Tia" or aunt, to brush his hair. Or this same motherly lady, dressed in a plain, striped seersucker uniform, might be helping 12-year-old Mary pack her school lunch. The father, Mr. G, is not there because he left about 7 a.m. to do odd jobs on a ranch nearby. He is 65 years old but he likes to supplement his Aid to Dependent Children check of \$96 per month by helping his "patron" repair fences, oil windmills, repair cattle guards (that's the kind of gate you run over the top rather than get out of a car and open), or anything else there is to be done. He does these odd jobs for \$4 or \$5 per day. The lady helping the children get off to school is our first homemaker. She has served continuously in this same home since January 24, 1955.

The situation of the G family came to the attention of the child welfare department in October 1953, when the mother became mentally ill and we had to place the children in foster-home boarding care. The mother was hospitalized, diagnosed as schizophrenic reaction, catatonic type with mental deficiency. With the prognosis poor, we decided it was unfair to keep the children in foster-home boarding care. Arrangements were made to return them to the father, Mr. G, who could use his ADC check of \$96 to pay a housekeeper to help him with the children, who were then aged 2, 5, 8, 10, and 11. This was a poor arrangement: Mr. G offered only \$1 a day to this helper. There was no washing machine. She complained of the two-burner kerosene stove and the fact there was no food except beans. She knew that this was not what a 2-year-old child needed. Mr. G fired her, only to find the next one just as complaining and disagreeable. When he did find someone to suit him, she quit because Mr. G did not want to pay her. "After all, I am furnishing the food," he said.

On January 24, 1955, the department employed a warm, motherly widow to work with Mr. G and his children during the days only. The children knew her because she had lived in the immediate neighborhood. Also, she knew the children's mother and was able to help them

understand and talk about what had happened. Each year the mother returns from the hospital on furlough to visit her family, but each time her peculiar behavior makes it evident to the children, the homemaker, and to Mr. G that she is too ill to remain at home.

In the meantime, our homemaker has taught the oldest girl how to cook, to sew, and to keep house. Plans are for this girl to take over the responsibilities of the home and to close the case during 1960, after 5 years of continuous service.

Our second homemaker was hired in October 1955, in an effort to protect five children, aged 2 through 15 years, from exposure to tuberculosis from their mother. Mrs. B, the mother, resisted hospitalization. Even though she went to the hospital several times, she would return home each time against medical advice. Enforced isolation of the mother in her own home, with a homemaker to care for the children, was the only alternative to foster-home boarding care for the children. When Mrs. B began hemorrhaging, she agreed to return to the hospital. Even then, she came home in 6 months for an "unauthorized" visit just to "see how the children were getting along."

The homemaker was able to give continuous 24-hour care to these children for 6 days each week, but not without problems. The father had always depended upon his wife to discipline the children, but he resented the homemaker doing it and he could not do this himself. As a day laborer in the fields, his income was insufficient even with ADC and this eventually was denied on the basis that a caretaker was supplied by the department. The homemaker was an excellent cook but, as a result of the ADC denial, there were times when there was little or nothing to cook. The homemaker accused the father of making "advances."

These issues were settled skillfully by the caseworker.

This same homemaker remained in the home of Mr. B's family until the mother was discharged after 3 years in the hospital.

Our program has grown and improved since those first few months of blundering and experimenting. At one time in 1959, we had 14 homemakers caring for 14 such families. In the past 4 years we have used a total of 57 home-

The Challenge of Disability

SURGEON GENERAL LEROY E. BURNEY

THE CHALLENGE of disability confronts every physician, whether he is a general practitioner or specialist, in private practice, in medical education, in public health, or in public medical care. It confronts members of all the health professions, as well as public and private welfare agencies. It confronts governments at every level, as well as legislatures.

The burden of disability falls with greatest severity upon disabled individuals, of course, and upon their families. But it affects every citizen, whether as employer, taxpayer, or community leader.

How does our society view disability? There is no doubt that in the United States disability is viewed with compassion, and as a burden which all of us must share with the disabled. Our programs to alleviate the financial burdens of disability and our rehabilitation programs for crippled children and disabled adults are the best evidence of our concern.

But I want to delve deeper into our attitude toward disability. I have observed wide variations in the kinds of services offered to disabled individuals in different countries. The underlying attitude, however, is very much the same. Disability is viewed by all societies as an accomplished fact; an unavoidable burden to be accepted—as our forefathers accepted all disease—as an act of fate or of some malevolent demon.

Dr. Burney, Surgeon General of the Public Health Service, delivered this address at the Governor's Institute on Rehabilitation, Honolulu, Hawaii, January 11, 1960. The paper on page 298, by Dr. T. Nishigaya, who is in private practice in Hawaii, was presented at the same meeting. Dr. Nishigaya's paper also appears in the March-April 1960 issue of the Hawaii Medical Journal.

To be sure, in countries like our own with highly developed medical skills and ample economic resources, there is a strong effort to alleviate disability. But in America and elsewhere we tend to apply the remedy after the fact—usually too long after. We have yet to develop an attitude which views disability as preventable.

If public health has a particular contribution to make in the field of rehabilitation, I believe that it is to foster an attitude of prevention. Prevention has been the first principle of public health since the birth of the modern movement. The earliest focus of attention, of course, was the prevention and control of infectious diseases. Over the years preventive measures applied by public health agencies and private physicians have averted an inestimable amount of prolonged disability, simply by the control of infections which left many survivors with crippling aftereffects. Many physicians in this audience will recall the frequent heart damage due to diphtheria, syphilis, and rheumatic fever. Most recently, the prevention of paralytic poliomyelitis, through the use of an effective vaccine, is rapidly reducing the accumulation of severely disabled persons due to that cause.

Today, the public health profession as a whole is as much concerned with high disability rates due to chronic conditions as it was with high mortality rates due to diphtheria and typhoid fever 60 years ago. The objective of this concern is to prevent the occurrence of chronic diseases, accidents, and dangerous environmental exposures if possible; if not, to prevent their disabling consequences.

Our Federal-State programs of public health and rehabilitation have one common objective; namely, reduction of the social and economic consequences of disability. Yet there are differ-

to recruit, get social security cards and health certificates, and to get to know the new homemaker, the mother is back at home before the homemaker is ready to work.

Homemakers are used primarily in situations where there are several children who would be dependent, neglected, and require boarding care in a foster home if homemaker service were not available.

We see this type of care for family groups as better for the children. First of all, it eliminates at least some of the trauma of separation. It keeps the father involved with his children's care at least at night and on weekends. The children need at least one parent and a closer family relationship than would be possible with boarding care.

It provides a type of care which the ill mother can accept more readily and thus it permits her to accept hospitalization. Many mothers have told us that they would stay in their home and die, rather than see their children "sent away" to some stranger's home. Of course, many factors encourage this attitude such as fear of the hospital—the unknown, and fear of the risk of leaving the husband.

We might mention a mistake we made early in the program. We hired some young, unmarried women who were alert and quite attractive. You can see how this failed. Even if things did go well at home, the ill mother in the hospital became jealous and left against medical advice in order to protect her place in the family. Now we seldom employ a homemaker who is not already a grandmother, and, as pointed out previously, one who is known and accepted by the mother. (Incidentally, the average age is 50 years.) We have given status to our homemakers in the eyes of the community and the children they serve by supplying each homemaker with plain striped seersucker uni-

forms with insignia. The insignia have "Child Welfare" at the top and "Homemaker" at the bottom. In the center is embroidered the face of a child. The insignia were handmade by a group of nuns in Mexico.

To justify the use of uniforms at county expense, I thought my best argument, stated briefly, was: "This uniform, like that of a nurse, sets these neighborly ladies aside as being officially in the home and not just another woman who has taken the place of the mother who is ill."

Casework services are provided when a homemaker is used. The caseworker has the difficult task of helping the father keep his place as head of the house by providing the groceries as well as giving the love and care he should to the children. She must also help the children to understand what has happened to the family. She keeps the hospitalized mother informed about the children with visits, letters, and pictures. There has not been a single instance of a mother returning home from a hospital against medical advice since our homemaker program has become well established. The homemaker, in planning the budget and in working through disciplinary problems with the father, has the aid and support of the caseworker. The welfare worker is, in a sense, the homemaker's employer, yet she must look to the father as the head of the house who provides the funds (usually ADC) for the children.

Our homemaker program is far from perfect, but it is serving a definite purpose for us in Texas by preserving families and saving them from having to go to foster homes. We experimented with needful families and found a partial solution in homemaker service. I hope others might be able, not to duplicate our program, but to apply those parts of it which might enable them to serve children better in their States and communities.

surviving today in a tragic sort of half-life. By very simple measures instituted promptly in the home or in the hospital, the majority of stroke patients can recover function within a short period of time. There is ample clinical evidence that more than 80 percent of patients who survive a stroke can become ambulant within two months with appropriate clinical management. The longer the physician waits to institute these measures the longer will the patient be disabled, and the more difficult it will be to restore function.

As the Nation's families and communities struggle with mounting burdens of long-term disability and dependency, are there no alternatives to high-cost care in hospitals and institutions? Fortunately, some States and communities have experimented and found that much disability can be prevented, and that many long-term patients can be cared for in their own homes, often more satisfactorily than in an institution.

The Georgia State Health Department, for example, in cooperation with the State Heart Association, medical organizations, and the Public Health Service is conducting a special program for stroke patients. There are approximately 40,000 survivors of strokes in the State. Often these patients have other serious medical problems and fill hospital beds over long periods of time. Prolonged bed rest, dependency, and speech difficulties generate severe disability, as well as psychological problems in these patients. Their disability creates social and economic difficulties for their families.

The Georgia stroke program includes education of the medical and nursing professions in the early use of physical therapy and early ambulation of stroke patients. A demonstration clinic is being conducted at Grady Memorial Hospital, the teaching hospital of Emory University Medical School. Here the stroke patients are seen on an outpatient basis and appropriate physical therapy is prescribed. The family is responsible for carrying out the therapy in the home. A public health nurse visits the home periodically to instruct the family and to supervise performance of the recommended procedures. A team composed of a physician, a physical therapist, and a public health nurse is

available to give intensive training in these procedures to physicians and nurses in local communities.

Another program, even broader in concept than that of the Georgia stroke program, is of interest. This is a home care program for disabled persons conducted in a rural county in North Carolina. It provides medical consultation, nursing, social service, physical and occupational therapy, health and nutrition education, orthopedic equipment, medicines, and sick-room supplies as needed. Residents of the county are eligible regardless of age, sex, or financial status, providing they possess a potential for self-care or self-support. All patients must be referred by a local physician and must remain under his care while receiving services of the program. The Public Health Service is co-operating with State and local agencies in this project.

A specially significant feature of this program, I believe, is its communitywide coverage. So long as community services are restricted to persons dependent on public welfare or to individuals with a potential for employment, medicine and public health will be neglecting the majority of the people needing care. In most rural areas, services such as are provided by this program have to be created. They are not available outside the hospital and many rural hospitals do not have the full range of services required for medical rehabilitation.

I have been told that the first patient to apply for the services of this home care program was a disabled woman whose financial resources are ample to support her for the rest of her life. She wanted to live in her own home rather than in some distant institution. Her inner drive for an active life sought the means for recovery. Her physician could not possibly provide all the services and facilities she needed to achieve this goal. Yet before the community home care program was established, there was no way he could bring the nursing service and special therapies to her bedside.

A few years ago, the Commission on Chronic Illness listed 32 services which patients with long-term conditions are likely to need at various times. While the average physician has his

(Continued on p. 299)

ences in approach. Public health strikes primarily at the causes of disability and hence must seek its opportunities for prevention among supposedly healthy individuals and in the community environment. Rehabilitation strikes primarily at the effects of disability and must seek its opportunities among individuals who are known to be disabled. Both programs are constructive at the core, in that both seek change for the better: change in health status for the whole community, change in the disabled status of the individual.

This determined effort to bring about change is a dynamic force in public health and rehabilitation. It is the force, I believe, which has brought the Public Health Service and the Office of Vocational Rehabilitation into a closer relationship during the past year. We realize more than ever before that our country cannot solve the medical and community service problems involved in disability by piecemeal approaches. Hence we are striving to plan and work together, so that the Service and OVR may more effectively mobilize their resources in a concerted attack on the causes and on the effects of disability.

Disability is a medical problem first and foremost. The success of the attack, therefore, depends primarily upon the alertness and action of each physician. As a social problem, disability can be alleviated by financial support of the disabled, by social services, vocational counseling and training, and placement in employment. It cannot be solved by these means, however, unless everything possible has been done to solve the medical problem.

The preventive approach to disability views the medical solution as beginning the moment a physician sees a patient whose condition obviously or potentially will lead to disability. The medical solution of disability continues as long as the patient needs medical services to sustain his highest potential of active life. This is the central fact which demands a broader view of rehabilitation than has been generally accepted in this country up to the present time. And it is the fact which demands the development of community medical services and the active participation of all physicians.

Rehabilitation services too often are planned around the problems of patients with static con-

ditions—the paralytic, the amputee, the blind. Our Federal and State laws related to employee compensation, social insurance, public assistance, and vocational rehabilitation tend to support this view of rehabilitation.

Another handicap to the medical solution of disability is the emphasis on the potential for competitive employment in public and some private rehabilitation programs. This criterion does not take into account the needs of elderly retired persons for rehabilitation services, nor of many severely disabled younger persons who, for one reason or another, do not present a significant potential for employment.

Changes in Community Needs and Services

The greater efficiency of medicine today warrants a much more flexible response to the challenge of disability. I should like to discuss with you briefly a few of the changes in recent years which focus attention on the role of medicine and public health in rehabilitation.

I need not summon an array of statistics to demonstrate the changes in the patterns of illness. Acute conditions, excluding injuries, account for smaller proportions of the Nation's mortality and prolonged disability. Chronic conditions and severe impairments are the major health problems. There are more older people in the population, and the incidence of chronic conditions increases with age.

Of equal significance, a larger proportion of acutely ill persons survives the initial attack or the injury which first brought them to the physician's attention. Delay in the institution of restorative medical services until the patient's condition has stabilized often means waiting until he has become "permanently and totally disabled."

The initial heart attack, for example, proves with increasing frequency to be the first episode of many. If the physician does not have in mind the prevention of disability from the outset, he may add another "heart cripple" to the increasing number of cardiac patients who are needlessly retired from active life by reason of their disease. Early return to an increasingly active regimen under careful medical supervision will avert many such cases.

There are untold numbers of stroke patients

surviving today in a tragic sort of half-life. By very simple measures instituted promptly in the home or in the hospital, the majority of stroke patients can recover function within a short period of time. There is ample clinical evidence that more than 80 percent of patients who survive a stroke can become ambulant within two months with appropriate clinical management. The longer the physician waits to institute these measures the longer will the patient be disabled, and the more difficult it will be to restore function.

As the Nation's families and communities struggle with mounting burdens of long-term disability and dependency, are there no alternatives to high-cost care in hospitals and institutions? Fortunately, some States and communities have experimented and found that much disability can be prevented, and that many long-term patients can be cared for in their own homes, often more satisfactorily than in an institution.

The Georgia State Health Department, for example, in cooperation with the State Heart Association, medical organizations, and the Public Health Service is conducting a special program for stroke patients. There are approximately 40,000 survivors of strokes in the State. Often these patients have other serious medical problems and fill hospital beds over long periods of time. Prolonged bed rest, dependency, and speech difficulties generate severe disability, as well as psychological problems in these patients. Their disability creates social and economic difficulties for their families.

The Georgia stroke program includes education of the medical and nursing professions in the early use of physical therapy and early ambulation of stroke patients. A demonstration clinic is being conducted at Grady Memorial Hospital, the teaching hospital of Emory University Medical School. Here the stroke patients are seen on an outpatient basis and appropriate physical therapy is prescribed. The family is responsible for carrying out the therapy in the home. A public health nurse visits the home periodically to instruct the family and to supervise performance of the recommended procedures. A team composed of a physician, a physical therapist, and a public health nurse is

available to give intensive training in these procedures to physicians and nurses in local communities.

Another program, even broader in concept than that of the Georgia stroke program, is of interest. This is a home care program for disabled persons conducted in a rural county in North Carolina. It provides medical consultation, nursing, social service, physical and occupational therapy, health and nutrition education, orthopedic equipment, medicines, and sick-room supplies as needed. Residents of the county are eligible regardless of age, sex, or financial status, providing they possess a potential for self-care or self-support. All patients must be referred by a local physician and must remain under his care while receiving services of the program. The Public Health Service is co-operating with State and local agencies in this project.

A specially significant feature of this program, I believe, is its communitywide coverage. So long as community services are restricted to persons dependent on public welfare or to individuals with a potential for employment, medicine and public health will be neglecting the majority of the people needing care. In most rural areas, services such as are provided by this program have to be created. They are not available outside the hospital and many rural hospitals do not have the full range of services required for medical rehabilitation.

I have been told that the first patient to apply for the services of this home care program was a disabled woman whose financial resources are ample to support her for the rest of her life. She wanted to live in her own home rather than in some distant institution. Her inner drive for an active life sought the means for recovery. Her physician could not possibly provide all the services and facilities she needed to achieve this goal. A few years ago, the Commission on Chronic Illness listed 32 services which patients with long-term conditions are likely to need at various times. While the average physician has his

(Continued on p. 299)

The Physician and Rehabilitation

The practice of rehabilitation for any physician begins with the belief and basic philosophy that the doctor's responsibility does not end when the acute illness is ended or surgery completed. It ends only when the individual is re-trained to live and work with what he has left. This basic concept of the physician's responsibility can be achieved only if rehabilitation is considered an integral part of medical services.

The physician has always practiced some aspects of rehabilitative therapy though he may not have thought of it as such.

Traditionally, the saving of human life and the relief of suffering were his primary goals. Those individuals disabled by congenital defects, disease, injury, or infirmities of age were accepted as having suffered the expected consequences of their difficulties and were regarded as hopeless.

Today, the fact that life is preserved does not necessarily mean that a good cure has been obtained. The diagnosis and treatment are often so absorbing that there is increasing danger of focusing too much attention on the disease without regard to the person as a whole. The true significance of rehabilitation and its real distinction from preventive and curative treatment rest on the conviction that both lay and medical resources can be used to prevent and treat those disabling complications.

Rehabilitation is every physician's business. Experience has shown that much of all rehabilitative processes can and should be done by the practitioner responsible for the patient's primary medical care. To meet the needs of the more difficult cases, the physician can refer patients to rehabilitation centers where a team approach can be applied, using the special skills of specially trained physicians, physical and occupational therapists, social workers, speech and hearing therapists, nurses, vocational counselors, psychologists, and prosthetics specialists.

These co-professional personnel act as members of evaluating and therapeutic teams. However, one person must be responsible since the patient cannot

effectively be treated by committees. This is the physician's responsibility. Medical guidance is necessary for rehabilitation to have purpose, for, regardless of the type of disability, the responsibility of the physician to his patient cannot end when the acute illness or injury has been cared for. In addition, because of the high prevalence of chronic illnesses and their tendency to be prolonged, the basic elements of early detection and adequate medical care must be complemented by rehabilitation. These services should continue as long as the patient can profit from them.

We must not lose, by neglect of the social and emotional life of the patient, those controls which are not affected by the illness. Custodial institutional care contributes to a deterioration of the patient far beyond what is inherent in the development of the disease itself. It is therefore essential that physically degenerative and socially degenerative processes that diminish the individual's capacity for self-maintenance be prevented, and that we direct efforts at the restoration of the capacity of the individual to maintain himself. We must protect the health of the patient though we cannot cure that part of him which is specifically diseased.

The patient must maintain some goal to his activity. This may mean a return to the status of self-help. It may mean employability, the traditional goal of rehabilitation efforts. Productivity has more than an economic connotation. In any case activity has an important social meaning in terms of the status of the individual.

We must emphasize that we are not dealing solely with physical disability but we are concerned with a person. We must consider and evaluate the patient's physical capacities and consider his vocational, psychological, and social status since these are important factors in his eventual social integration.

Medical care is not complete until the patient has been trained to live and to work with what he has left.

—T. NISHIGAYA, M.D., *Honolulu, Hawaii*

patient in the hospital, most of these services, plus the basic provision of bed and board, are made available as a matter of course. He takes such services for granted, scarcely realizing that nowhere else in the community will his medical decisions be so scrupulously put into practice. The physician is responsible for making the diagnosis and prescribing the treatment, but an army of professional and ancillary personnel carry out his orders—in the hospital.

These so-called "supplementary services," and the men and women who render them, now play a more important role in the delivery of medical services than the physician himself. In 1900, three in every five professional health workers were physicians; in 1950, only one in five were physicians. The problem that confronts the physician, as keyman in combating disability, is how to marshal these supplementary services in effective management of his patients—in his office and in their homes.

Public health, with its community-oriented approach, is in a strategic position to help resolve this dilemma of modern medical care. Chronic disease, mental disorders, and the problems of aging may be regarded as the "growing edge" of both prevention and rehabilitation. The benefits from application of the wealth of knowledge in both fields are still largely potential. They will remain largely potential, I fear, until all physicians—in private practice, in administrative positions, and in hospitals—recognize and act upon their responsibilities in these fields. I place this burden on our entire profession for the simple reason that these are medical problems, and the action of other groups in health related services stems from the physician's initiative.

What nurse, for example, will begin the measures which will restore function in a stroke

patient—unless the attending physician has specifically prescribed these measures? What personnel manager or supervisor will properly adjust the cardiac patient's work schedule—unless the physician has clearly prescribed the patient's 24-hour schedule of working and living activities? What local health department will allocate its often meager resources to home services for the disabled—unless the medical society endorses such programs, and practicing physicians use the services?

I have tried to present to you this evening some of the changes that are affecting medicine, public health, and rehabilitation. I have shared with you some thoughts on the challenge of disability and how we may meet it with greater confidence. It will not be easy to stimulate a fresh view of disability as a preventable evil. Even with the great scientific advances, the medical solution of disability will not be easy. It is up to us to try.

A first step is for men and women in the fields of medicine, public health, and rehabilitation to get to know each other better. Better understanding of one another's aims, methods, needs, resources, and problems; better communication—these will lead us into better ways of working together for the goals we all want to attain.

Let us also work together for the patient in his community. This means that we must work toward better organization of community services, better balance in our programs, earlier application of preventive methods in the care of all patients. We must do so if our material resources, with a shrinking dollar and a shrinking supply of competent personnel, are to suffice in making a significant impact on disability.

Signs

and

Symptoms

of trends in public health

A newly opened \$1½-million addition to the University of Michigan School of Public Health doubles its teaching and research facilities. Two 4-story wings have been attached to the original building, erected in 1913.

Laboratories for research in epidemiology, industrial and radiological health, and sanitation are being housed in the new wings. In addition, there are multipurpose lecture rooms and workshops, radiation laboratories with lead-lined walls, library facilities, and a 2-story laboratory for testing large equipment.

The new structures, financed in part with funds from the Public Health Service and the Kellogg Foundation, house research equipment valued at one-quarter of a million dollars.

« »

Accidental release of 3,000 pounds of hexavalent chromium to the Raisin River in Michigan imperiled several municipal water supplies last December. The State Health Department and Water Resources Commission alerted towns to close intakes at water plants as the slug approached. They stayed shut for 12 hours.

« »

Chemical and biological research in water, sewage, and industrial wastes at Ohio State University will expand in a new \$180,000 Water Resources Center, scheduled for completion May 1960.

The facility, now under construction, was financed by a grant from the Public Health Service and State appropriations.

Homemaker Service, a community program administered by the Family Service Association of Greater Boston, has a staff of 110 homemakers who last year served more than 1,200 families. Forty-four homemakers receive a guaranteed annual wage; the others are paid for the amount of time worked. Mrs. Elinor McCabe, the director, and her social workers receive and study all applications and place and supervise the homemakers.

Local departments of public welfare in the Greater Boston area purchase this service for selected public assistance families at a rate of \$12.25 a day. The local department considers this expenditure an administrative expense which is outside the area of Federal financial participation. Through the use of this community service, many public assistance families are able to remain together or continue to live in their own homes when illness or disability occurs.

« »

At a cost of more than \$5 million, the Institute for Muscle Disease has been completed in New York City.

"To increase our knowledge of muscle, to understand the mechanisms by which muscular dystrophy and other muscular disorders arise, and to develop treatments for these conditions," is the primary objective stated by director Dr. Ade T. Milhorat.

« »

In Keene, N.H., 13 cases of typhoid fever were traced to a single lumberman, a carrier, working in the watershed. Chlorination had been suspended.

Per capita health expenditures from tax funds in Connecticut ranged from \$1.20 to \$2.25 during 1958, it is reported in the December 1959 issue of *Connecticut Health Bulletin*. Broken upon population groups by towns, the statistics show that health expenditure on a per capita basis rises with increase in town population.

Expenditures by individual towns within population groups, however, differ markedly. In towns under 1,000 in population, for example, with an average per capita expenditure of \$1.20, one town spent 26 cents per capita while another spent \$3.

« »

Quantities of strontium-90 in American water courses sampled weekly by the Public Health Service in 1959 ranged from 0.0 in the first and second quarters at Alsea, Oreg., to an average of 4.8 micromicrocuries per liter in the third quarter at Chattanooga, Tenn. The maximum permissible for lifetime exposure of the general population is 80. Early readings at Hoover Dam were reported as relatively high but a recheck established a low rating of 0.9.

« »

Indianapolis was influenced by the etiological relationship between housing and mortality in enacting an up-to-date housing ordinance, as drafted by the committee on the hygiene of housing of the American Public Health Association, according to Dr. Henry J. Nester. He said, "I have found it particularly interesting to note that you have a lower force of mortality in those parishes with higher percentage of houses provided with toilets, baths, and hot and cold running water."

« »

Conservation of hearing in Madison County, Miss., is the object of a public program to screen hearing defects among about 9,000 school children, with the use of an audiometer donated by the local Lions Club, which also contributes to the operator's salary.

Funds for the correction of identified hearing defects in indigent children will be supplied by the Lions Club and the School Health Service.

A comparison of the rates of native and foreign-born admissions to public mental hospitals in Ohio during a 4½-year period tends to support earlier findings that migration rather than foreign birth per se is significant in the comparative incidence of mental disease.

Immigration and Insanity

BEN Z. LOCKE, M.S., MORTON KRAMER, Sc.D.,
and BENJAMIN PASAMANICK, M.D.

INFORMATION on mental illness among the foreign-born is sparse and very little is current. Indeed, in a recently published book the data in the section on nativity pertained to the period 1917-34 (1). Also, aside from gross national data derived from the decennial census of institutions, most of the detailed available information on this subject concerns admissions to mental hospitals in but three States: Minnesota (2), Massachusetts (3), and New York (4-6).

This paper reviews these early data and presents the rates at which native and foreign-born were admitted to Ohio public mental hospitals during the period 1948 to June 30, 1952.

Historical Review

In the introductory remarks of the 1880 census (7) it was stated that "The extraordinary ratio of insanity among the foreign-born has attracted wide attention." However, this report pointed out that "the question of age has a bearing upon the comparative num-

ber of the insane who are of native and of foreign birth" and that "the difference disappears, in large measure, when, instead of comparing the number of insane with the total population, we compare it with the population above the age at which insanity ordinarily occurs, that is to say above the age of 15 years. I have here put the margin very low." As a result of this simple but incomplete correction for age it was shown that "instead of the foreign insane being 2½ times as numerous, in proportion, as the native white insane, they are about 50 percent more numerous."

The 1910 census (8) also pointed out that while "the foreign-born have an unduly large representation in insane asylums" the ratios "if regarded as an index of the tendency to insanity among immigrants as compared to the native population are misleading." It then states that "the age difference probably goes further than any other factor toward explaining the contrast between the native white and the foreign-born white in respect to the proportionate numbers admitted to hospitals for the insane." Other factors it mentions as relevant are sex ratios, geographic distribution, and the degree of concentration in cities besides the migration factor and the concomitant consequence of a changed environment involving "new physical, economic, and social conditions."

However, in analyzing mental disease admission rates in Minnesota for the four decades

Mr. Locke serves as chief of the Consultation Section, Biometrics Branch, National Institute of Mental Health, Public Health Service. Dr. Kramer is chief of the Biometrics Branch, and Dr. Pasamanick is director of research of the Columbus Psychiatric Institute and Hospital, College of Medicine, Ohio State University.

from 1889 through 1929, Ødegaard reported that the standardized first admission rates among the Norwegian born were significantly higher statistically than the rates for the native-born (2). In his analysis, Ødegaard stressed the importance of initial selection and the problems of assimilation, but for each decade analyzed the difference in the standardized admission rates between the two groups decreased.

In presenting his findings regarding nativity and mental disease in Massachusetts, 1917-33,

Dayton also stated that "Early reports on the relative incidence of mental disorder in the foreign-born and in the native-born favored the native-born in a very decided manner. Later it was discovered that the greater part of the observed differences between the two nativity groups was statistical rather than actual . . ." (3).

The Massachusetts data, in which age was fully considered, showed the foreign-born to have higher first admission rates than the native-born. But as Dayton pointed out, the

Table 1. First admission rates per 100,000 to Ohio public mental hospitals of white persons, by age, sex, nativity, and residence, all diagnoses, 1948 to June 30, 1952

¹ Age-adjusted rates based on total native-born Ohio population.

NOTE: The numbers of admissions are for the entire 4½-year period; the rates are on an average annual basis.

Figure 1. Average annual first admission rates to Ohio State public mental hospitals, for white males, by age, nativity, and residence, all diagnoses, 1948 to June 30, 1952

native-born had certain protections which might have tended to keep him out of the hospital. The foreign-born was not only handicapped by the absence of these protective mechanisms (familial, social, and economic) but had language difficulty as well. Another factor, although a minor one, was the greater use of private facilities by the native-born.

Malzberg, in his study of first admissions to all institutions for mental disease in New York State, 1929-31, found "that even after age differences had been eliminated, the foreign-born still had a higher rate of first admissions than the native-born, though the excess was much less than that derived solely on the basis of crude rates" (4). However, after reviewing the data from several aspects he comes to the general conclusion that the available data indicate few, if any, differences in the relative incidence of mental disease among native and foreign whites in New York State that cannot be accounted for adequately on the basis of environmental and age differentials.

In a similar study involving 1939-41 data, Malzberg and Lee minimized the importance of the overall differential of 11 percent among males. They took the 21 percent difference in age standardized rates for total psychoses in

Figure 2. Average annual first admission rates to Ohio State public mental hospitals, for white females, by age, nativity, and residence, all diagnoses, 1948 to June 30, 1952

females as evidence of an important difference in the patterns of first admissions by nativity of white females (5).

Based on the 1939-41 data, Malzberg stated that a population native to a given environment has lower rates of mental disease than the population in the same environment which is of foreign birth (6). This conclusion was qualified by the statement that the more we compare the two populations on a comparable basis, the greater is the approximation in rates of first admissions.

Ohio State Study Results

According to the 1950 census, 5.6 percent of Ohio's population was foreign-born, and 19 States had larger percentages (9). New York had the highest percentage foreign-born, 16.8; Massachusetts had 15.2 percent; and Minnesota 7.0 percent. In Ohio, the 1950 foreign-born white population numbered slightly over 440,000.

During 1948 to June 30, 1952, there were 2,692 foreign-born white first admissions to the Ohio public mental hospitals (aged 10 and over). In the same period, 20,720 native-born whites were admitted. As shown in table 1, the crude rates for the foreign-born are much

higher than those for the native-born. Age, the same factor to which attention was called in the 1880 census, appears to account for part of the disparity in these crude rates. In Ohio, for example, the median age of the foreign-born and native-born whites, was, respectively, 42 and 19 in 1880, 39 and 24 in 1910, and 57 and 30 in 1950. Nevertheless, when the 1950 rates were adjusted for age, the rates remained higher for the foreign-born, as would be expected since figures 1 and 2 and table 1 show

that for most age groups the rates were either at the same level or higher for the foreign-born.

In the New York State study, the differential in rates between the foreign-born and the native-born females was such that Malzberg and Lee stated: "The poorer showing of all foreign-born females relative to natives tends to substantiate Odegaard's hypothesis that females make less satisfactory adjustments to migration than do males, or alternatively that female immigrants are not as well 'selected' as are male

immigrants" (5). The Ohio data substantially agree with the findings of Ødegaard and Malzberg.

However, had the rates of first admission for foreign-born and native-born been alike after age adjustment, it would not have been an indication that there are no true differences in their respective incidence of mental illness. It had been mentioned earlier that there were forces, such as lack of family and language, and economic and other problems of assimilation, that might have tended to increase the rate of hospitalization among the foreign-born.

It is also conceivable that cultural differences might have tended to keep some of the foreign-born out of hospitals unless very ill. Also, screening of immigrants and deportation of others may have been more diligently carried out since the 1930's. The proof of not becoming public charges may have raised their level of socioeconomic and educational status somewhat.

Nevertheless, given the current volume of immigration, the factor foreign-born per se does not seem to warrant much attention. What should command considerable concern is the factor of migration. White and nonwhite males and females born in Ohio had lower rates than their counterparts who were born elsewhere in the United States and subsequently migrated to Ohio (table 2 and figs. 3 and 4). Malzberg and Lee in analyzing the New York State data also found that the rates for native

Figure 4. Average annual first admission rates to Ohio public mental hospitals for native-born females, by age, color, and place of birth, all diagnoses, 1948 to June 30, 1952

migrants, regardless of color or sex, are strikingly higher than those for persons born in the State (5). Despite the agreement of these two studies, replication for other areas as well as other periods of time is needed. Furthermore, as Dorothy S. Thomas stated in her introduction to "Migration and Mental Disease," such studies must be extended to include analyses of differentials between migrants and nonmigrants in areas of origin as well as in areas of destination (5).

Advantage should be taken of the 1960 census. Information regarding migrants (native-born and foreign-born) by such factors as household composition, marital status, education, and occupation could be obtained for mental patients and correlated with information obtained at the time of the 1960 census. In addition, the psychiatric diagnosis of the patients should be considered in the analysis. Such studies require large numbers of patients. It might be that several States would have to collect, in a comparable fashion, data which could be pooled and analyzed to provide this needed information about mental illness among migrants, both native- and foreign-born.

Meteorological Aspects of Large Scale Air Pollution

LESTER MACHTA, Sc.D.

THE practicing weather forecaster cares very little about the composition of the air aside from its water vapor content. But we are beginning to realize that there is more to meteorology than advising the public whether or not it will rain tomorrow. We live in the atmosphere and it is important that we keep it as clean as possible. Man's dispersal of wastes into the air has become so enormous that in certain areas, particularly urban ones like Los Angeles, the atmosphere is at times incapable of providing adequate local dilution.

Though pollution by cities of their own immediate locality is a major concern, we should keep in mind that most pollutants are not destroyed by disposing of them downwind of a city. Under some circumstances, the pollutants of many cities combine and affect areas far removed from the sources of pollution. Ultimately, if the exponential growth of industry with its waste disposal problems continues, contamination may become global, making further dilution impossible. When pollution becomes a worldwide problem, the allowable releases will depend on the atmosphere's cleansing ability.

The consequences of air pollution reach beyond immediate effects such as damage to health

and agriculture. They affect the weather as well. There is strong evidence that increased atmospheric contamination reduces visibility and modifies electrical conductivity, precipitation, and the radiation balance. What subtle and far-reaching effects will result from these and other phenomena are now unknown.

Our present aims in studying the meteorology of air pollution are measurement, understanding, and prediction. Unfortunately, none of these reduces the amount of pollutant put into the atmosphere. But through the proper selection of industrial sites, local contamination can be minimized; through meteorological detective work, an offending culprit can be uncovered; and through forecasting, pollutants can, in principle, be withheld pending a return to conditions more conducive to dilution.

The major effort in meteorological research of air pollution is on a microscale—citywide contamination. At present, a meteorological analysis is considered successful if a way is found for the pollutants to be vented into the atmosphere without local difficulties. By the time the effluent reaches the next city, diffusion is expected to reduce concentrations to a satisfactory level. But there are exceptions even today. For example, Dr. C. D. Keeling of the Scripps Institution of Oceanography at La Jolla, Calif., almost 100 miles south of Los Angeles, says that he has often watched the carbon dioxide concentration rise from 310 to 340 ppm as a brown cloud from the north descends on his observation post. Similarly, it has been estimated that 15 percent of the organic partic-

Dr. Machta is chief of the Special Projects Section, Office of Meteorological Research, U.S. Weather Bureau. This article is based on a paper given at a symposium on the physics, chemistry, and biology of the atmosphere, published in the proceedings of the National Academy of Sciences, December 1959.

Community Cancer Demonstration Project Grants

For the current fiscal year, Congress has appropriated \$1,500,000 for community cancer demonstration project grants. The Cancer Control Branch, within the Division of Special Health Services, Public Health Service, is administering the fund and is receiving applications from health agencies and nonprofit organizations and institutions. Additional projects may be approved during spring and summer of 1960.

Among types of projects believed to offer the best opportunities for demonstrating better ways of providing community cancer control services are:

- Professional and technical education in cytology.
- Screening female beneficiaries of medical care for cancer of the cervix.
- Selected educational projects, particularly public information and followup services, to emphasize the importance of periodic uterine cytology examinations.
- Professional educational activities emphasizing the importance of including cancer diagnostic aids in complete health examinations.
- Selected public educational projects on the desirability of and need for health maintenance examinations.
- Evaluation of effectiveness of public educational activities.
- Tumor registers collecting data of exceptional value.
- Extension and evaluation of rehabilitation programs (in cooperation with State rehabilitation agencies).

- Selected projects demonstrating effective treatment for cancer in public beneficiaries of medical care.

The types of projects suggested are not meant to exhaust all possibilities. Other worthwhile locally sponsored and locally directed demonstration projects will be considered on their own merits.

Applications are accepted from nonprofit organizations and institutions and official health agencies. The appropriate State health officer and Public Health Service regional medical director first review and process applications. The requests are then submitted to the advisory committee and the advisory council for recommendation of approval or disapproval. Formal action on applications and recommendations is taken by the chief of the Bureau of State Services, Public Health Service, to whom authority has been delegated by the Surgeon General.

Projects may be approved initially for as long as 3 years. When activities proceed satisfactorily and funds are available, assistance continues through the approved period. In special instances, assistance may include the assignment of personnel and the provision of equipment and supplies. Additional information and application forms may be obtained from the eight regional offices of the Public Health Service.

The Cancer Control Branch and its Advisory Committee believe that much can be done to reduce illness and death from cancer now, especially from cervical cancer.

ulates measured at Louisville, Ky., originate outside the area of Greater Louisville.

The areawide air pollution problem will be with us in the near future, if it is not here today. Meteorological study of this larger problem has so far succeeded in identifying the weather conditions conducive to large-scale air pollution episodes and confirming the relation between these conditions and high concentrations of pollutants.

The Warm High

We think there are three weather factors which favor air pollution episodes on a broad scale: first, small dilution due to light winds and a low altitude thermal inversion which inhibits upward mixing; second, the absence of rain scavenging; and third, the persistence of this weather for several days, permitting pollutants to accumulate.

This weather fits the description of a warm high-pressure system. It is entitled a "warm" high because, unlike a polar mound of high pressure, the air within it is warm in comparison to the surrounding atmosphere. Insofar as I am aware, every important air pollution episode, Donora, London, and Meuse Valley has occurred during the passage of a warm high-pressure system. In Los Angeles, episodes coincide with this weather system, but other meteorological and topographical factors are also important. Orographic features and sources of pollutants determine where and when an episode will occur during the presence of a warm high-pressure system.

We can illustrate the significant factors with surface weather maps which are typical of a slow-moving warm high. Figure 1 shows the surface weather charts during 4 successive days of the well-known episode at Donora, Pa., in October 1948. The thin lines are isobars. The heavy lines mark the separation between warm and cool air masses. Shaded areas show regions of rain. A center of high pressure on the first day of the series is in southern Ohio. On successive days it moves erratically over the eastern United States, a typical situation.

The speed of wind at ground level and in the first few thousand feet of air is more or less inversely proportional to the spacing of the

isobars. From these maps it is evident, first, that the weak pressure gradient associated with the wide spacing of the isobars in the region around the center of high pressure results in very light winds. Local ventilation is severely restricted by this condition. Second, the air mass making up the high pressure is sinking. The result is a low-level thermal inversion, with a base at about 3,000 feet in the afternoon and lower at other times. This inversion acts like a lid, preventing upward mixing. Because of clear skies the nocturnal outgoing radiation is intense, building up a very strong nighttime ground thermal inversion which likewise inhibits vertical mixing. In the London and Donora episodes, the air cooled enough to produce fogs which could not be burned off by the daytime solar heating.

When a large area of the United States is dominated by such a slowly moving high-pressure system, the normal, fairly rapid west-to-east airflow is replaced by air which drifts about slowly and irregularly. Pollutants from one city are more likely to be added to those of another in appreciable concentrations. The absence of vertical mixing confines all of the contamination to the layer of air near the ground.

In a study of potential atmospheric contamination from nuclear reactors, Pack and Hosler (1) have analyzed the effects of a stagnant meteorological pattern upon atmospheric dilution over the densely populated and industrialized Middle Atlantic States. To do so, they determined the spread of effluents if they were released continuously for a 36-hour period from eight hypothetical locations during an actual stagnant weather system.

They selected a slowly moving weather system that occurred October 11-16, 1956. During all 5 days of this weather pattern, a warm high-pressure system was quasi-stationary over the Middle Atlantic States. The system was attended by light winds at the surface and the first few thousand feet above the ground. An intensifying subsidence inversion, based at about 3,000 feet, accompanied the high-pressure cell, while ground thermal inversions prevailed during nocturnal hours.

Pack and Hosler's analysis, illustrated in figure 2, is based on the following assumptions:

Figure 1. Surface weather charts for October 27–30, 1948, during the air pollution episode at Donora, Pa.

An intensifying subsidence inversion, based at about 3,000 feet, accompanied the high-pressure cell, while ground thermal inversions prevailed during nocturnal hours.

Pack and Hosler's analysis, illustrated in figure 2, is based on the following assumptions:

Figure 2. Plumes of effluents which would be created by 36 hours' continuous release from 8 locations under the weather conditions of October 12-13, 1956

(a) effluent is carried at the speed and direction of the surface wind; (b) the plume diffuses 11° laterally in each 6 hours of movement; (c) vertical spreading of the plume is limited to within the mixing layer, that is, the estimated depth of the well-stirred lower atmosphere at the time of maximum afternoon temperature; and (d) effluent is uniformly distributed within the volume defined by the first three assumptions, except for the material dispersed during the most recent 6-hour period, which maintains a separate and distinct geometry of distribution.

In figure 2, the shading for the most recent 6-hour plume traverse is more intense to distinguish it from the older, more dilute cloud of effluent. The irregular paths are apparent: more important, this diagram illustrates the reinforcement of several plumes from many sources as a result of time and space variations. For instance, effluents from New York, Hartford, Philadelphia, and Allentown all contribute to pollution of the area just west of Allentown, Pa.

It is possible to compute average concentrations of pollutants for this model, since the volume of air in the plumes can be readily es-

timated. By Pack and Hosler's calculations, 5×10^{12} cubic meters is the minimum volume of air into which the effluent in a single plume would be released in a 36-hour period. If 10,000 tons of carbon monoxide—the amount released in Los Angeles in 2 days—were diffused in a 48-hour plume, an average concentration of 1 ppm would blanket the area over which the plume extended.

Finally, the hypothetical situation depicted by Pack and Hosler accounts for the movement and overlapping of effluents from only eight locations in the Middle Atlantic States. It underestimates the actual cases of overlap, since there are many additional sources of pollution in this heavily industrialized area.

Forecasting Episodes

In 1957, an experimental program was established to associate predictions of stagnant warm high-pressure systems with measurements of pollutant concentrations. One objective of the program is to make sure that the stagnant warm high-pressure system is the one to which meteorologists should direct their attention.

Techniques developed under the program were applied to the eastern United States in a study covering the period September 1 through November 15, 1958. The weather criteria which had to be met in order to predict a potential for above-normal accumulation of pollutant were:

1. Surface winds of less than 8 knots.
2. Windspeeds no greater than 25 knots at any level below 20,000 feet.
3. Evidence of sinking motion at levels below 15,000 feet.
4. Continuation of the preceding three conditions for at least 36 hours.

Air quality data were collected from the study area by stations of the National Air Sampling Network. Niemeyer (2) showed from examination of the data that, with few exceptions, highest dust loadings occurred during the five periods when warm high-pressure systems were predicted to, and subsequently did, overlay the area. This experiment demonstrated that it is feasible to use forecasts of large-scale weather features to delineate periods of high air pollution potential over large areas.

Radon

Radon is a naturally occurring radioactive gas which is emitted from the ground. It has been amply demonstrated that ground-level radon concentration increases remarkably when atmospheric vertical mixing becomes weak. For example, nighttime ground-level concentrations are higher than daytime concentrations.

We have also studied radon concentration during the passage of a slow-moving warm high-pressure system. The system we selected occurred in Washington, D.C., in late October 1954. Through the courtesy of Dr. Luther Lockhart of the Naval Research Laboratory, the measurements of radon concentration in Washington recorded for that time were made available to us.

Figure 3 shows the average diurnal cycles of radon concentration in Washington before, during, and after passage of the warm high, or stagnation period, of late October 1954. Average windspeed during the 89 hours of stagnation was only 4.7 knots. It is apparent from the figure that significantly higher radon concentration occurred while the warm, stagnant high lay over Washington than either before or after its passage. The shaded area identified by "poor data" corresponds to the period of the daily filter changes when the radon decay products were not yet in equilibrium.

Figure 3. Average diurnal cycles of radon concentration in Washington, D.C., before, during, and after passage of a stagnant warm high-pressure system, October 1954

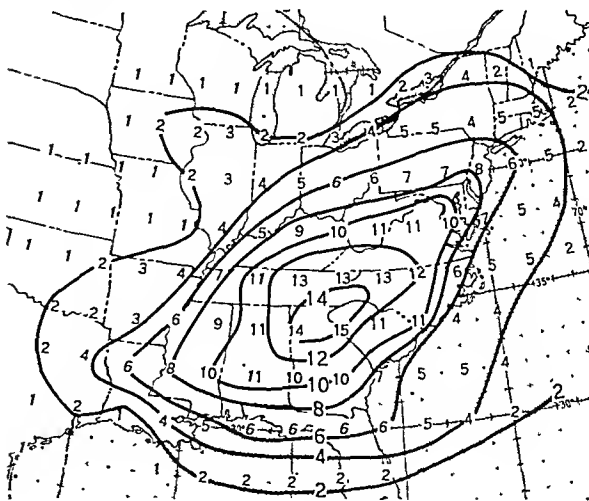

Figure 4. Occurrences of stagnant warm high-pressure systems during the month of October, 1936-1956

Further study of radon observations may reveal other applications for this type of data to air pollution problems.

Geographic Frequency Distribution

Korshover (3) has studied the spatial and temporal frequency distribution of stagnant warm high-pressure systems for the United States east of the Rockies. The maximum frequency occurs in the southern Appalachian Mountains and decreases radially from this area. Analysis of cases by months reveals a pronounced maximum frequency in the month of October.

Geographic distribution of the frequency of October stagnant warm highs is shown in figure 4. The numbers on the figure denote the frequency during a 21-year period of cases with 4 or more successive days of light winds (under 8 miles an hour). The heavy lines indicate equal frequency of occurrence. This October weather coincides with pleasurable memories of Indian summer, a period of unusually fine weather after the heat of real summer has waned.

It may be surprising to note the high frequency of cases, even in winter, when warm high-pressure systems cover the southeastern United States. Some of these instances result from extension of the Bermuda high-pressure

cell onshore, much farther west than its normal position. It seems probable that with equal industrialization, air pollution complaints would be more numerous in the Southeast than, say, in New England with its stormier weather.

Conclusion

I have described some meteorological aspects of large-scale air pollution, a problem almost certain to become aggravated in the future. The best way of avoiding air pollution episodes is by preventing dispersion of wastes into the atmosphere. Failing that, there are two ways the meteorologist can assist: first, along with health officials, he can monitor the atmosphere's cleanliness. Second, he can continue his efforts to devise adequate methods for predicting the dilution, transport, and removal properties of the atmosphere in case meteorological control becomes necessary—that is, permitting the re-

lease of pollutants only at times when weather conditions favorable to dilution have been forecast.

I suspect that in many ways the meteorologist is ahead of others in working on problems in this broader scale of air pollution.

INTRODUCTION

SEAT BELTS

ALVIN R. LEONARD, M.D., M.P.H., ALBERTA W. PARKER, M.D., and BARRY MILLER, M.D.

THE HEALTH DEPARTMENT of Berkeley, Calif., has launched a pilot safety campaign based on information collected by the automotive crash injury research program at Cornell University which suggested that the use of seat belts in automobiles would reduce accident fatalities by at least 25 percent (1). The decision to launch the campaign was predicated largely upon the conclusion of John O. Moore, director of the Cornell project, who stated that "it is our opinion, based on the relatively massive evidence available, that seat belts are the most important single economically feasible device available to control trauma associated with automobile accidents throughout our Nation" (2).

Projected, the Cornell figures mean that 5,500

Dr. Leonard is director of public health for the city of Berkeley and clinical professor of public health at the University of California. Dr. Parker is assistant director of public health in Berkeley and a lecturer at the University. Dr. Miller, at the time of the project, was a resident physician in the Berkeley City Health Department on assignment from the Public Health Service.

lives could have been saved in the United States by the use of seat belts during 1957.

On the principle that safety education begins at home, a program to encourage seat belt use among staff members of the Berkeley City Health Department was instituted in November 1958 (3). Objectives of the program were:

1. To provide a demonstration to the community emphasizing that the health department considers use of seat belts to be an effective means of minimizing injury and preventing death from automobile accidents.
2. To prevent serious injury and death among health department staff members and their families.
3. To provide a pilot study which might be useful to other organizations in identifying the problems encountered in promoting such a program.

Since the staff of the Berkeley Health Department uses private cars for city business, the cost of purchase and installation of the seat belts had to be borne by the employees themselves. It was decided at the outset to seek a lower unit price through group purchase.

"Operation Seat Belt" was supported vig-

consistency throughout the department. A series of monthly departmental staff meetings, attended by most employees, was devoted exclusively to installation and use of seat belts. Benefits of seat belts were presented by showing the motion picture "Impact," which was discussed by an officer of the State highway patrol. The Cornell studies were summarized by the field representative assigned to the automotive crash injury research project in the California State Department of Public Health. Employees were given detailed information concerning the value of seat belts in reducing serious injury and death. Each meeting allowed a period for questions and discussions.

To insure participation throughout the department, a seat belt committee of representatives from each group was formed. It sought by questionnaire to ascertain how many employees already had seat belts and how many would like to share in the group purchase.

Of 53 employees owning automobiles, 5 already had at least 1 seat belt installed. Forty-four had no seat belts, but were interested in acquiring them. Four had none and were not interested. There were six employees who did not own automobiles.

Reasons given for disinterest were "I can't afford them" or "I do city driving primarily and my understanding is that seat belts are useful only on the highway." The view that seat belts are of no value in the city appeared to persist despite explanations that many fatalities occur through accidents in town, which could be prevented by their use.

The California Highway Patrol tests seat belts and lists those which meet acceptable standards (4). This list was used in selecting the seat belt to be purchased. A choice of two brands was offered. Group purchase reduced the cost to the individual by approximately one-half of the retail price. (An additional saving on insurance is potentially possible, since some insurance companies grant reduced premiums in covering medical expenses and disability for car owners who use seat belts.)

Installations were handled by individual garages; this was not included in the group purchase price of the seat belts. Variations of make and model of car tend to command price differences for installation. All installations

National Seat Belt Campaign

During the last year the Public Health Service joined forces with the National Safety Council and the American Medical Association in a campaign to educate the American public as to the value of automobile safety belts and to encourage the widespread use of this device.

Research has established that at least 5,000 lives could be saved annually if occupants were not thrown from motor vehicles when accidents occur, and the severity of injuries experienced in motor vehicle accidents is lessened when occupants are restrained by safety belts.

Each of the three national organizations cooperating in this campaign is making every effort to use its own machinery and resources to the utmost in attaining the goal of universal acceptance of safety belts as a "standard" feature of the American automobile.

The Accident Prevention Branch of the Public Health Service has worked with State and local health departments in implementing this project, and has aided in the development of many local campaigns. All public health workers may be proud of the enthusiasm and energy displayed by communities such as Berkeley, Calif., in encouraging the use of seat belts.—DR. PAUL V. JOLIET, *chief, Accident Prevention Branch, Public Health Service.*

followed instructions of the manufacturers, and the belts were secured to the frame if possible.

Additional resistance to the installation of seat belts, which had not emerged in the preliminary survey of interest, was expressed by several staff members at the time of actual purchase. First mentioned was the cost. Then, some of the women staff members were concerned lest the belts possibly wrinkle their clothing. Other staff members stated that their work in the field necessitated many stops and starts and the repeated fastening and unfastening of seat belts would be a nuisance and a waste of time.

Fear of death resulting from being trapped inside an automobile in an accident involving fire or water caused some anxiety and uncertainty also. In this connection, it is noted that

some newspaper reports of accidents in which wearers of seat belts were drowned or burned were misinterpreted to mean that the seat belts had been the cause of the accidents. Even though various facts and figures were cited to show that in the vast majority of motor vehicle accidents water and fire are not important factors, it was difficult to allay some of these apprehensions.

During the months following, other objections to seat belts came to the attention of the health department's committee from sources outside the department. Some of these were: "Good drivers don't need seat belts." "Drivers using seat belts have a false sense of security and become overconfident." "Seat belts have a negative psychological effect on safe driving." Objections such as these may arise within any group undertaking a seat belt program. Approximate answers to these and other objections are offered in the literature available (5). In most instances where resistance was encountered or fear expressed, a well-informed committee member discussed the issue with the individual concerned. This personal approach worked well.

"Operation Seat Belt" was a completely voluntary program. No administrative pressure was applied. Installation of the seat belts was accomplished efficiently with little if any loss of staff time.

As a direct result, 106 seat belts were purchased by 38 employees. Two other employees who had not had seat belts at the time of the preliminary survey purchased them independently. Including the 5 employees who already had seat belts, 45 of the 53 employees who own automobiles, or 85 percent of the potential, now have seat belts in their cars. Among the eight who do not, several have indicated that they may acquire them.

Following these events in the health department, a similar program was conducted by employees of the public school system. An initial goal of this program was the sale of 100 seat belts to teachers. However, this was far exceeded in a short time: more than 450 seat belts were purchased by teachers. Students in the adult driver training program purchased an additional 206.

The Berkeley police department, which also makes use of personally owned cars for city business, is encouraging officers to equip their cars with seat belts. Currently, about 50 percent of the members of the department have seat belts in their automobiles.

The health department is strongly recommending to the city government that it have seat belts installed as standard equipment on all city owned vehicles in order to achieve reduction in death, injury, disability, man-days lost from work, and possibly, a saving in insurance premiums.

The example of these official agencies has had its expected influence in the community (6). For example, a large retail consumers' cooperative is now conducting a campaign for the sale and installation of seat belts among its members.

Discussion

The current epidemic of traffic accidents should be viewed within the concept of preventive medicine. Man's perception of preventive medicine is dependent on the period of time and the geographic location in which he lives. It is also dependent upon his culture or subculture, since different cultures exhibit wide variations in their concepts of ability to control the obvious threats to health and life.

In the development of preventive measures, there are essentially three stages: the stage when there is no scientific knowledge available, the stage when there is scientific knowledge available but it is not being applied by a significant number of the population, and the stage when there is scientific knowledge which is being effectively applied.

Until recent years we were in the first stage in respect to poliomyelitis. Today we are still in this first stage of not having the scientific means of preventing deaths from such diseases as cancer of the pancreas, most cases of leukemia, multiple sclerosis, and many others. Historically, our forebears were in this helpless situation with high maternal and infant mortality rates and high death rates from the various plagues.

The primitive reaction to such situations is either the adoption of a completely fatalistic

attitude, with the hope that the threat will not strike, or the use of various mechanisms prevalent in the culture, such as magic incantations, the use of symbolic objects, or other equally noneffective rituals to ward off the danger. Such attitudes and actions, although of dubious value, are not inappropriate to the first stage when there is really no effective measure for dealing with the hazard.

Such behavior, however, is entirely inappropriate when a society is in the second stage, when there is knowledge which is not being effectively applied. This is the situation in which we find ourselves today in regard to automobile accidents. We are both the perpetrators and the victims of a cultural lag. A scientifically proved preventive measure is not being applied, with a resultant needless loss of thousands of lives, and the needless occurrence of tens of thousands of disabilities. The psychological attitude of fatalism and the acceptance of a feeling of helplessness in automobile accidents contributes to the death toll and reinforces the attitude of fatalism, creating a vicious cycle. This cycle must be broken.

If there were 5,500 needless deaths annually from poliomyelitis, public health workers would take action immediately. If not, the American public would fast lose confidence in public health, and rightly so. When motor vehicle accidents are reviewed, however, it becomes quite apparent that not only the average person driving his car along the Nation's highways and freeways, but we who are specialists in the prevention of disability and disease seem to share the fatalistic approach to this common hazard to health and life. By our inaction, we have shown surprising apathy and lethargy in setting an example of effective leadership in preventive medicine. An inescapable responsibility of public health is to provide leadership in the community in moving from stage two to stage three.

Summary

Experience in Berkeley indicates that a local health agency is in an excellent position to set the pace for the community leaders in encouraging the use of automobile seat belts as a protection to automobile passengers and drivers. The use of seat belts is only one aspect of an extremely complex safety process. Safety is a total community responsibility, including the responsibility of the automobile designer, manufacturer, and vendor. Highway injuries and sequelae affect all segments of society. In a drive to achieve primary as well as secondary prevention, a health service works with other agencies such as police and fire departments, safety councils, county medical societies, community hospitals and emergency facilities, the schools and their driver training courses, and trade or manufacturing associations. Their combined efforts are needed to exert effective influence toward safe driving and toward the use of devices which will minimize and reduce death and disability on the streets and roads.

A Fatal Case of Rabies in a Woman Bitten by an Insectivorous Bat

GEORGE L. HUMPHREY, D.V.M., M.P.H., GRAHAM E. KEMP, D.V.M., M.P.H., and
E. GLENN WOOD, M.D.

RECOGNITION since 1953 of widespread rabies infection in insectivorous bats, native to the Western Hemisphere north of Mexico, has raised considerable conjecture regarding the potential of transmission to man and other animals and the role such a reservoir may play in the ecology and epidemiology of rabies (1-4). While the ecology of rabies in insectivorous bats is largely unknown, it is established that the virus may be present in the salivary glands and saliva (2, 4-10) and that some infected specimens may apparently harbor the virus as symptomless carriers (1, 2, 8, 11, 12). Whether this situation existed previously and is only now being recognized or is of recent origin is not known. Johnson (13) is of the opinion that rabies in bats is of recent origin. Since 1953, there have been numerous reports in the United States of persons being bitten by bats. Some of the animals have been rabid, some not rabid, and others were not secured for rabies examination.

Although epidemiological evidence has slowly accumulated incriminating insectivorous bats as a source of rabies infection for man (14-16) and while transmission from a naturally infected insectivorous bat to laboratory mice has been demonstrated (6), there has been no unequivocal evidence that rabid insectivorous bats have in-

fecting man or other animals in nature with the exception of the case to be described here.

A fatal case of rabies in a California woman definitely incriminates the silver-haired bat, *Lasionycteris noctivagans*, a free-living, insectivorous species, as a source of the disease for man.

History of Exposure

On Saturday, August 30, 1958, a 53-year-old woman picked up a bat that was lying on the ground near the porch of her home in Magalia, Butte County, Calif. In attempting to place it in a tree where her two dogs would not further molest it, she was bitten on the middle finger of the left hand.

The bat apparently appeared abnormal, for she telephoned a veterinarian, Dr. W. H. Martin of Paradise, Calif., about treating the bat for a broken wing. Dr. Martin, upon hearing she had been bitten, suggested the bat might be rabid and advised the woman to refrigerate the animal and notify the Butte County Health Department. Because of the Labor Day weekend the health department was not notified until Tuesday, September 2.

The county health department laboratory examined the bat's brain and reported it positive for Negri bodies. A portion of the brain and the carcass of the bat were forwarded to the California State Department of Public Health. Identification of the bat and additional laboratory findings will be described later.

On the basis of the county laboratory's posi-

Dr. Humphrey and Dr. Kemp are with the veterinary public health section, bureau of acute communicable diseases, California State Department of Public Health in Berkeley. Dr. Wood practices medicine in Paradise, Calif.

tive findings, the woman was administered 3,000 units of hyperimmune antirabies serum intramuscularly late on September 2, the third day after she was bitten. The following day Dr. Wood began a course of rabies vaccine. The vaccine, of duck embryo origin (17-19), was administered in 14 daily injections.

At the time this treatment was initiated, the bite wounds consisted of two small healing punctures in the region of the second interphalangeal joint of the middle finger of the left hand. Local treatment was not administered because of the time interval between the bite and the healing of the wounds.

Eight days after administration of the anti-serum and 7 days after the start of the vaccine therapy, the patient developed a skin rash with severe pruritis. Daily administration of the antihistaminic drug pyrilamine maleate was begun, and the next day strontium bromide with calcium gluconate was added to the therapy. However the rash persisted until shortly after the series of 14 doses of rabies vaccine was completed. At no time were members of the corticosteroid group of drugs administered.

The woman apparently remained well until October 24, 1958, when she went to a local chiropractor complaining of numbness in the inner left arm, extending to the first two fingers, and of pain in the region of the third thoracic vertebra. She returned with the same complaints the next day. On October 26, the pain descended to the fifth or sixth thoracic vertebra, and she complained also of gas and pressure below the diaphragm. From October 27 through 29, her chief complaint was abdominal pain. The chiropractor, as far as is known, was unaware of the bat incident.

The chiropractor became increasingly concerned about the possibility of an intestinal obstruction and repeatedly urged her to enter a hospital. On October 29 she visited Dr. Wood with the complaint of acute abdominal distress. She was treated symptomatically and told to return if she was no better in the morning. Since there was no improvement in her condition, she was admitted to a local hospital at 9:40 a.m., October 30. The diagnosis on admission was possible intestinal obstruction and notations of pain in upper left abdomen, intermittent for 10 days. On November 4 the woman

died, 66 days following exposure, 49 days after antirabies treatment had been completed, and 11 days after onset of symptoms. (See clinical history during hospitalization, p. 320.)

Laboratory Findings

An autopsy was performed approximately 13 hours after death. The only gross pathological finding was a 12-inch section of ileum, black in color and definitely delineated.

Bat and human brain material were submitted for further investigation to the virus and rickettsial disease laboratory, California State Department of Public Health, by the county health department. Findings are reported in full elsewhere (20) and are summarized here.

Microscopic examination of tissue impressions of the human brain material, stained by Sellers method (21), by the county health department and the State Department of Public Health, and examination of tissue sections by the State agency all revealed the presence of intracytoplasmic inclusion bodies not characteristic of Negri bodies. The histopathological picture was a diffuse nonsuppurative encephalomyelitis with the midbrain and brain stem especially affected.

Suspensions of the bat brain and the human brain material both proved infective for mice, and mouse brains all contained Negri bodies. The agent recovered from the human brain was further confirmed as rabies by serum neutralization test, using hyperimmune antiserum of equine origin.

Other Possible Exposures

The husband of the deceased woman told Dr. Kemp that he knew of no exposures experienced by his wife other than the bat incident. The two dogs that may have encountered the bat and two cats on the premises at the time of the incident were still in good health on March 3, 1959.

The husband recalled that he had observed fecal droppings on a porch of the house on most mornings during the summer prior to his wife's exposure. From his description, these appear to have been bat droppings, and the porch probably served as a night roosting site, perhaps for the moribund bat that his wife found. No

Photograph by Ernest P. Walker, National Zoological Park, Smithsonian Institution
Silver-haired bat (*Lasionycteris noctivagans*)

droppings were observed after the date of the biting incident.

During the winter, the husband stored boards in piles on the superstructure of his small sawmill, which is adjacent to the house. Early each spring when he moved the boards to spread them out over the superstructure of the mill for shade, he said that he frequently uncovered bats between the boards.

The Silver-Haired Bat

The carcass of the bat which had bitten the woman was identified as a silver-haired bat, *L. noctivagans*, by Keith F. Murray, mammalogist, bureau of vector control, California State Department of Public Health, and confirmed by Seth Benson, Ph.D., Museum of Vertebrate Zoology, University of California, Berkeley.

L. noctivagans (see photo), the only species in its genus, is distributed widely over the northern part of North America. It inhabits for-

ested areas and characteristically roosts under loose slabs of bark on trees. The species is infrequently encountered, although it is probably fairly common in suitable areas. Colonies have been found in the eastern part of the United States, but, in general, it is a solitary or free-living bat.

It is generally accepted to be a migratory species. In California, although there is no clear evidence of migration, scattered records suggest movement to lower elevations in winter. The observed distribution in California is primarily in the northern forest areas, the Sierra Nevada range, and along the coast south to Monterey County.

Butte County in northern California is divided into the Sierra foothills, which support open growths of blue oak woodland, Ponderosa pine forest beginning at 2,000 feet, and Douglas fir forest, beginning at 3,000 feet. There is a Ponderosa pine forest in the immediate vicinity

of the house where the biting incident took place. About 1 mile distant is a large, fresh-water reservoir.

L. noctivagans has been found to be rabid in at least two other recent instances. One oc-

curred in Osoyoos, British Columbia, in August 1958. A bat found in an old shoe bit a 75-year-old man on the thumb and index finger of the left hand. Brain tissue and salivary glands of the animal, a mature female silver-haired bat,

Clinical History During Hospitalization

First hospital day. Meperidine hydrochloride, an analgesic, phenothiazine chlorpromazine, a depressant, and secobarbital sodium, a sedative and hypnotic, were administered as required. Roentgenographic gastrointestinal studies revealed essentially negative findings. An electrocardiogram showed an abnormal picture which was interpreted as myocardial strain.

The results of blood studies follow:

Red blood	
count-----	4,650,000 (appears slightly hypochromic)
Hemoglobin-----	87 percent, 13.6 gm.
White blood	
count-----	16,300
Total polymorphonuclear leukocytes-----	91
Non-segmented-----	1
Segmented-----	90
Eosinophiles-----	0
Basophiles-----	0
Total lymphocytes-----	5
Monocytes-----	4
Myelocytes-----	0

Temperature ranged from 96.3° to 98.0° F., pulse from 75 to 80, and respirations from 12 to 20 per minute.

Second hospital day. The patient complained of pain in the abdomen, arms, and back and was extremely restless. Urinary incontinence was noted, and she was reported to have been immodest before visitors. She was again given meperidine hydrochloride and phenothiazine chlorpromazine. Neostigmine, a parasympathetic nerve supply stimulant, phenobarbital, belladonna, and atropine were also administered. A urinalysis revealed largely negative findings with the exception of large amounts of acetone.

The patient's temperature ranged from 98.2° to 98.6° F., her pulse from 88 to 102, and respirations from 15 to 24 per minute.

Third hospital day. The patient had a good appetite for breakfast but ate little in the latter part

of the day. She had poor muscular control of the extremities and complained of pain in many parts of her body. She was again given meperidine hydrochloride, phenothiazine chlorpromazine, belladonna, and, in addition, acetophenetidin-acetylsalicylic acid-caffeine.

Fourth hospital day. The patient complained of severe pain, especially in the abdomen and down the legs. She ate well, however. Late in the day she became restless and tossed and turned a great deal. She was given meperidine hydrochloride, phenothiazine chlorpromazine, belladonna, secobarbital sodium, and phenobarbital.

The results of a spinal fluid examination were: appearance—clear; white blood count—none; protein—120 mg. percent; sugar—77 mg. percent; and Pandy test—positive.

Temperature ranged from 98.6° to 99.6° F., pulse from 70 to 100, and respirations were 20 per minute.

Fifth hospital day. The patient was extremely restless, complaining of pain in her stomach and inability to eructate and pass flatulence. She stated she was unable to feel hypodermic injections, yet complained of wrinkles in the bedsheets. She had less control of her extremities than on previous days but ate an evening meal. She was again given meperidine hydrochloride, phenothiazine chlorpromazine, and belladonna. Her temperature rose continuously from 99.8° at 7 a.m. to 102.2° F. at 7 p.m. Her pulse ranged from 96 to 112 and respirations were 20 to 34 per minute.

Sixth hospital day. The patient complained of abdominal distress and inability to swallow the mucus which ran almost continuously from her mouth. She also complained of a feeling of heaviness in her chest. She deteriorated rapidly in the afternoon. Temperature, pulse, and respirations all rose briefly in the early afternoon to 102.4° F., 120, and 30 per minute, respectively, and dropped just prior to death, which occurred at 6:30 p.m.

were inoculated into four mice each at the animal pathology laboratory, Canada Department of Agriculture, in Vancouver. Between the 11th and 14th postinoculation day, all mice were dead. Microscopic examination revealed typical Negri bodies (5).

Another silver-haired bat, submitted from Pueblo, Colo., in 1959, was reported positive by the South West Rabies Investigation Station, Las Cruces, N. Mex. (22).

Rabies in Nonsanguivorous Bats

Prior to 1953 rabies in bats was believed limited to the geographic areas inhabited by the vampire bat—Mexico, Central and South America, and Trinidad (23). Although a few isolations had been made from frugivorous and insectivorous species of bats in Brazil (24) and Trinidad (25), these were considered to be infections related to the vampire reservoir and were thought to play no role in the spread of the disease.

The first identification of rabies in a nonsanguivorous bat in the United States was made from a Florida yellow bat, *Dasypterus floridanus* (12,26). The bat was killed while unprovokedly biting a 7-year-old boy in daylight on June 24, 1953, in Florida. On September 23, 1953, a bat attacked a woman standing at a lake front in Boiling Springs, Pa. (27,28). The carcass was inadvertently destroyed but it is believed to have been a hoary bat, *Lasiurus cinereus*. In both instances the bats were confirmed as rabid by laboratory examination. Both persons received antirabic treatment and remained well.

Haupt and Rehaag (24) reported a leaf-nosed bat, *Phyllostoma superciliatum*, biting a calf which later developed paralytic rabies. Bell (6) achieved transmission of rabies by the bite of a naturally infected California myotis bat, *Myotis californicus*, on three of a litter of six mice.

Since the initial isolation of rabies virus from an insectivorous bat in Florida in 1953 (12,26), rabies has been identified in nearly 300 bats of 19 bat species, 4 solitary and 15 colonial, from 19 States in widely divergent areas of the United States (personal communication from E. S. Tierkel, Communicable Disease Center,

April 30, 1959). The greatest number of isolations has been made in the southwest.

Bat-Associated Rabies in Humans

While the transmission of rabies infection from the vampire bat to man has been well authenticated (25), we are aware of only five reported instances of rabies in humans associated with insectivorous bats other than the case reported here. The first case, reported by Sulkin and Greeve (14), was in a 43-year-old woman who died of rabies in Texas in 1951. She stooped to look at a bat lying at the side of a road near her home. The bat flew up and bit her on the left forearm. Sixteen days later she became ill. She was admitted to a hospital 5 days later with a diagnosis of bulbar poliomyelitis. She died on the fourth day she was in the hospital. Negri bodies were observed on microscopic examination of brain tissue. The bat was neither identified nor examined for rabies.

The second case occurred in India (15). A railway worker, 48 years old, noticed some boys pelting a bat with stones. He was bitten viciously on the forearm when he attempted to place the bat in a tree. He went to a physician 3 months later complaining of malaise and difficulty in swallowing. He had a temperature of 100°F. His condition deteriorated rapidly and he died on May 24, 1954. The species of bat was not identified nor was it examined for rabies.

The third case, reported by Irons and co-workers (16), was in a Texas State Health Department entomologist who died of rabies on January 4, 1956. He had been engaged in research on bat rabies in Texas, capturing, handling, and banding insectivorous bats in caves from April through November 1955. Isolation of rabies virus had been made from bats taken from the caves where he had worked. He had also inoculated bats with rabies virus several months before his death. How and when he was infected even he did not know. He is known to have worked extensively, however, in Frio Cave, Uvalde County, a cave which figures prominently in the history of the fourth case. Rabies infection in the entomologist was confirmed by positive mouse inoculation test.

The cause of death in the fourth case has been

Rabid bats found in California, January 1, 1954–December 31, 1959

Year, month, and county	Species	Results of mouse inoculation test	Remarks
1954			
July, Sonoma-----	<i>Tadarida brazil- iensis</i> .	Combined brain and sal- ivary gland tissues positive.	Survey specimen, apparently healthy, collected near Forrestville.
1955			
June, Kern-----	<i>Myotis californicus</i> ---	Salivary gland tissue pos- itive, brain liquified, not examined.	Found dead in fish pond at Camp Yen- Hante on Green Horn Mountain.
September, Madera--	<i>Tadarida brazil- iensis</i> . ¹	Brain and salivary gland positive.	Bat observed in tree by man pruning tree in Madera. Man bitten captur- ing bat. Bat dead next morning. Brain Negri negative. Neutraliza- tion test positive.
1956			
August, Santa Clara--	<i>Myotis species</i> ¹ -----	Brain tissue positive-----	Bat unprovokedly attacked boy and grandfather in patio of home in Los Gatos about 5:30 p.m. Boy bitten behind ear.
September, Shasta---	<i>Lasiurus cinereus</i> -----	Brain tissue positive-----	Apparently paralyzed bat observed on porch steps of home in East Redding. Dog possibly bitten. Negri positive.
September, Shasta---	<i>Tadarida brazil- iensis</i> .	Brain tissue positive-----	Partially paralyzed bat observed at noon crawling across floor of motor- cycle shop in Redding. Negri nega- tive.
October, Butte-----	<i>Lasiurus cinereus</i> -----	Brain tissue positive-----	Partially paralyzed bat found in yard of home in Chico. Negri negative.
1957			
July, Madera-----	<i>Tadarida brazil- iensis</i> . ¹	Brain tissue positive-----	Apparently partially paralyzed bat observed to fall out of tree on a ranch. Negri negative. Neutraliza- tion test positive.
September, Madera--	<i>Myotis evotis</i> -----	Brain tissue positive-----	Bat scared off ground during daytime in Agnew Meadows, High Sierras. Lit on nearby tree, then lit on second tree. Man bitten capturing bat. Negri negative.
1958			
April, Shasta-----	<i>Tadarida brazilensis</i> ---	(?)-----	Partially paralyzed bat found lying on porch of county health department below known bat roost in roof tiles. Negri positive. Neutralization test positive.
June, Butte-----	<i>Tadarida brazil- iensis</i> . ¹	Brain tissue positive-----	Two dogs observed playing with par- tially paralyzed bat in yard of home in Thermalito. Not known if dogs bitten. Negri negative.
August, Butte-----	<i>Lasionycterus noctivagans</i> .	Brain tissue positive-----	Partially paralyzed bat picked up by woman who was bitten and sub- sequently died of rabies. Negri pos- itive.
September, Butte---	<i>Lasiurus cinereus</i> -----	(?)-----	Partially paralyzed bat found in yard of home in Chico. Negri positive.
July, Alameda-----	<i>Tadarida brazilensis</i> ---	Brain tissue positive-----	Partially paralyzed or dead bat found by 7-year-old boys in Berkeley. Boys incurred skin punctures, but not known if due to bite. Negri negative.
July, Kern-----	<i>Tadarida brazilensis</i> ---	Brain tissue positive-----	Paralyzed bat found under bat roost in Kern Canyon. Died next day. Negri negative. Neutralization test posi- tive.

Rabid bats found in California, January 1, 1954–December 31, 1959—Continued

Year, month, and county	Species	Results of mouse inoculation test	Remarks
November, Kern-----	<i>Lasiurus cinereus</i> -----	Brain tissue positive-----	Partially paralyzed bat found by three children in Bakersfield. Children apparently not bitten. Negri negative.
December, Imperial--	<i>Macrotus californicus</i> ---	Brain tissue and saliva positive.	Apparently healthy bat collected in survey from mine near Potholes. Neutralization test positive.
1959			
April, Alameda-----	<i>Tadarida brasiliensis</i> ---	Brain tissue positive-----	Partially paralyzed bat found during daytime floundering on garage floor of home in Centerville area. Negri negative.
May, Kern-----	<i>Lasiurus cinereus</i> -----	Brain tissue positive-----	Three of 13 apparently ill or abnormal bats captured at the Naval Ordnance Test Station, Ridgecrest, Inyokern, during daytime or early evening. All Negri positive.
May, Kern-----	<i>Lasiurus cinereus</i> -----	Brain tissue positive-----	
June, Kern-----	<i>Antrozous pallidus</i> -----	Brain tissue positive-----	
June, Marin-----	<i>Antrozous pallidus</i> ---	(?)-----	Two cats found playing with a partially paralyzed adult bat on front porch of home in San Rafael at 3 a.m. Bat bit one cat. Negri positive.
June, Marin-----	<i>Antrozous pallidus</i> ---	(?)-----	Partially paralyzed young adult bat found being played with by dog in yard of home in San Rafael during evening. Negri positive.
June, Marin-----	<i>Antrozous pallidus</i> ---	(?)-----	Young bat just beginning to fly found dead under bush by dog in yard of San Rafael home. Negri positive.
August, Marin-----	<i>Antrozous pallidus</i> ---	Brain tissue positive-----	Partially paralyzed young adult bat found being played with by cat in patio of San Rafael home at noon. Microscopic examination atypical.
June, Napa-----	<i>Antrozous pallidus</i> ---	(?)-----	Partially paralyzed bat found on ranch near Calistoga. Negri positive.
July, Napa-----	<i>Tadarida brasiliensis</i> ---	Brain tissue positive-----	Partially paralyzed bat found near Calistoga. Microscopic examination atypical.
July, Butte-----	<i>Lasiurus cinereus</i> -----	(?)-----	Partially paralyzed bat found by ranger in Bidwell Bar State Park near Oroville. Negri positive.
July, Butte-----	<i>Pipistrellus hesperus</i> ---	Brain tissue positive-----	Partially paralyzed bat found in swimming pool of Butte County Hospital, Oroville, by child. Child picked up bat and was bitten. Microscopic examination atypical.
September, Butte---	<i>Tadarida brasiliensis</i> ---	Brain tissue positive-----	Bat found being played with by cat in Chico home. Cat bitten. Microscopic examination negative.
July, Modoc-----	<i>Pipistrellus hesperus</i> ¹ ---	Brain tissue positive-----	Partially paralyzed bat found in yard of home in Alturas. Negri negative.
August, Shasta-----	<i>Tadarida brasiliensis</i> ---	Brain tissue positive-----	Partially paralyzed bat found alive on front step of home in Redding. Microscopic examination atypical.
September, Glenn---	<i>Tadarida brasiliensis</i> ---	Brain tissue positive-----	Partially paralyzed bat found on step of school in Willows by school child. Microscopic examination atypical.
September, Ventura--	<i>Lasiurus cinereus</i> -----	(?)-----	Bat made unprovoked attack upon dog in daytime in home at Fillmore. Negri positive.
October, San Joaquin--	<i>Tadarida brasiliensis</i> ---	Brain tissue positive-----	Found moribund in street in Tracy.

¹ Identification of species probable.

² Results of mouse inoculation test not available.

confirmed but how the infection was incurred is not clear (29). A consultant mining engineer died of rabies in Wadsworth Veterans Administration Hospital, West Los Angeles, Calif., on June 3, 1959. He is known to have explored bat caves in the Big Bend country of Texas as possible locations for mining bat guano. Between April 17 and 28, 1959, he visited Hawkey Cave, Pecos County; Frio Cave, Uvalde County; Fern Cave, Val Verde County; and Dunbar Cave, Edwards County.

He told a friend that in one cave, believed to be Frio Cave, the bats were very numerous and he had had to hold his flashlight above his head to protect himself. During this time a bat nicked him in the face. However, prior to death he was emphatic in denying that he had been bitten by a bat or other animal. He also visited Mexico during the periods April 9-14 and May 11-14, but is thought not to have visited bat caves there.

On May 26 he became nauseated and vomited, and complained of pain in his left hand and arm. He was admitted to the hospital June 1.

The clinical history following hospitalization is one of dyspnea, Cheyne-Stokes respiration, periods of depression, continuous retching, hypersensitivity, anxiousness, sweating, hydrophobia, rapid deterioration, and death. Temperature was just above normal on hospital admittance and reached 103° F. terminally. A clinical diagnosis of rabies was reached early on June 2. Death occurred on June 3.

Microscopic examinations of brain material by the Los Angeles City Health Department and the University of California at Los Angeles Medical School were negative for Negri bodies. Mouse inoculation tests by both laboratories revealed a pathogenic agent, which killed the mice in 6 days, but examination of the mouse brains failed to reveal Negri bodies. The identity of the mouse pathogenic agent as rabies virus was confirmed by positive serum neutralization tests in mice and the finding of Negri bodies in the brains of second passage mice.

The fifth case occurred in a 44-year-old man in Wisconsin (30a). On August 8, 1959, a sleeping farmer in Blue River was bitten on the lobe of the right ear by a bat that flew in the window. On August 29 he complained of tingling and pain in the area of the right ear.

He died on the morning of September 4, 1959. Microscopic examination of brain tissue taken at autopsy revealed Negri bodies and mouse inoculation test was positive for rabies. The bat incident was the farmer's only known contact with a possible rabies vector. The bat was not identified or examined for rabies because it was eaten by the family cat.

Bat Rabies as a Public Health Hazard

Evaluation of the role of bat rabies in the epidemiology and ecology of the disease in the United States is extremely difficult. Despite the widespread reservoir of the disease in bats the evidence of transmission from bats to terrestrial animals is negligible.

The direct public health hazard of rabies in bats is likewise somewhat difficult to evaluate. cursory review of various reports of human exposures in this country and Canada indicates at least 75 persons have been reported to have been bitten (31). The actual number of persons bitten by bats certainly is greater than the reported figures indicate. In the majority of reports which include the circumstances of the bite the bitten persons subjected themselves to exposure through handling an abnormal- or ill-appearing bat.

Few reports (6, 12, 14, 26-28, 30) indicate unprovoked attack. These circumstances closely parallel experience in California (see table).

The first recognition of bat rabies in California was made in 1954 (11). Subsequent recognitions have brought the total number to 35, comprising at least 8 species from 14 counties.

Two of the 35 were apparently normal specimens collected in surveys. Two were found dead, one in a fishpond and one on the ground. Twenty-eight were ill, partially paralyzed or moribund when found. One was disturbed, during daylight, on the ground by the bitten person.

Only two bats made unprovoked attacks, one on a boy and his grandfather and one on a dog.

Of persons exposed in California, five (three adults and two children) are definitely known to have been bitten; two children may possibly have been bitten; and three children were contacts, but apparently not bitten. Eleven do-

mestic pets (seven dogs and four cats) have been contacts to rabid bats in California. With but one exception, all persons bitten in California exposed themselves by handling bats which exhibited signs of abnormality, such as partial paralysis.

A total of 92 cases of rabies in humans were reported in the United States during the 8-year period 1951-58, of which only 3 were associated with exposure to bats, an incidence of about 3 percent. Thus, the available evidence indicates the hazard of direct transmission of rabies from bats to man is minor compared with that of transmission from terrestrial animals.

Discussion of the Case History

The woman in the case history related earlier received what is usually considered to be an adequate course of antirabic treatment (32), initiated within 3 days after exposure. Despite the treatment, she succumbed to rabies 66 days following exposure and 49 days after completion of treatment. The case clearly represents an instance of treatment failure. The nature of the bite wounds and the size of the animal to which she was exposed would seem to preclude the possibility of implantation of an overwhelming inoculum of rabies virus. There is nothing in the woman's past history to suggest undue susceptibility to infection, such as agammaglobulinemia.

Summary

On August 30, 1958, a woman was bitten on a finger of the left hand by a silver-haired bat (*Lasiurus noctivagus*) near Magalia, Butte County, Calif. The woman was bitten during unnecessary handling of the bat which behaved abnormally. The animal was proved rabid by the finding of Negri bodies in impressions of bat brain material and isolation of rabies virus by mouse inoculation. The patient was administered what is usually considered to be an adequate course of antirabies treatment, initiated on the third day following exposure. Treatment consisted of 3,000 units of hyperimmune antirabies serum followed by 14 doses of rabies vaccine of duck embryo origin. Although treatment was complicated by a skin rash, the

woman remained well until October 24, 1958, when she complained of numbness in the left arm and fingers and of pain between her shoulders. Her condition gradually deteriorated, becoming complicated by an ascending paralysis. Death occurred on November 4, 1958. Rabies virus was isolated from her brain and identified by serum virus neutralization test. The case constitutes an instance of antirabies treatment failure.

The case is believed to be the first fully documented instance of transmission of rabies from nonsanguivorous bat to man.

Present knowledge of the extent of the insectivorous bat rabies reservoir in the United States and five other human cases of rabies associated with insectivorous bats are reviewed. The public health hazard of rabies in insectivorous bats is discussed.

OVR's "Rehabilitation Record" Makes Debut

Rehabilitation Record, a journal to be issued every 2 months by the Office of Vocational Rehabilitation, Department of Health, Education, and Welfare, published its first number January 1960. It reviews activities of the Federal-State program of vocational rehabilitation, with emphasis on research supported by OVR. Subscription rates are \$1.75 a year (overseas, 50 cents additional), payable to the Superintendent of Documents, U.S. Government Printing Office, Washington 25, D.C.

Environmental Health in Pennsylvania

CONFERENCE REPORT

AT the environmental health session of the 8th Annual Pennsylvania Health Conference, papers presented ranged from power reactors to fish killings. The program chairman was Karl M. Mason, director of the bureau of environmental health, Pennsylvania Department of Health.

George Elias, regional sanitary engineer for the southeastern region, told how models of the Delaware River Basin are presently being used to predict effects of river pollution on tidal waters. The use of the model, in which the State department of health is participating

financially, removes much of the guesswork from the predictions of tidal action in the Delaware River. Some industries located in the Delaware River Basin find that wastes discharged during one period of the day are carried upstream by the tide and enter their water intakes later.

Victor Sussman, chief of the air pollution section, explained the progress of Pennsylvania's air pollution legislation currently under consideration. He drew attention to chapter 200 of the 1959 California State law which states that "The State Department of Public Health shall, before February 1, 1960, develop and publish standards for the quality of the air

of this State. The standards shall be so developed as to reflect the relationship between the intensity and composition of air pollution and the health, illness, including irritation to the senses, and death of human beings as well as damage to vegetation and interference with visibility."

"Why Bother about Silicosis?" was answered by Dr. Jan Lieben, director of the division of occupational health, who stated that the majority of the 2,957 Pennsylvanians who died of silicosis during the past 2 years were coal miners. He said that foundry workers and stonecutters also ranked high in the silicosis fatality toll. Lieben stated that deaths caused by silicosis topped the 2,032 deaths from tuberculosis, and ranked only slightly lower than lung cancer as a killer. Lung cancer caused 4,600 deaths during the 2-year period. The disease, Lieben said, results from inhalation of certain dusts. The disease is preventable and is entirely dependent on the amount and quantity of dust entering the lung tissues. Lieben said silicosis costs Pennsylvania an estimated \$15 million annually to pay workmen's compensation claims of those disabled by the disease.

On the subject of power reactors, Donald Lazarchik, sanitary engineer with the division of sanitary engineering, stated that Pennsylvania will have 13 $\frac{1}{3}$ percent of the Nation's total nuclear power generating capacity by 1963. He said, a concentrated effort in power reactor research has been in the development of pressurized water reactors similar to those used in nuclear-powered submarines and that of the nuclear power generating plant at Shippingport. The Shippingport plant, he stated, has successfully operated more than 5,000 full power hours and for the first 560 days of operation has discharged less than 6 percent of the wastes allowed by the health department in the unidentified category. Less than 2 percent of the allowable concentration of tritium was discharged, and the gaseous wastes were much less than anticipated.

Another experimental reactor is planned at Saxton in Bedford County. This power generating station is being built with the express purpose of reducing costs to levels of conventional power plants. Lazarchik stated that conventional power plants cost from \$100

to \$200 per kilowatt of installed capacity while at present most nuclear power plants cost \$300 to \$100 per kilowatt. In an effort to reduce costs to a competitive basis, 52 privately owned utility companies have formed a company known as High Temperature Reactor Development Associates, Inc. This corporation plans to build an advanced concept power plant at Peach Bottom, York County, Pa. According to the engineers, the plant looks very promising because of its simplicity, economy of operation and construction, and its inherent safety.

Lazarchik stated that the nuclear power industry produces less than 1 percent of the Commonwealth's electrical consumption and presents no problem today with widely scattered power plants. If the trend of power consumption continues to double every 10 years and we assume widespread use of the atomic power, it may be difficult to cope with the resulting problems and to determine the effect of these plants on the environment, he cautioned.

The needs in radiation research were discussed by Dr. Ursula I. Nitch of the division of occupational health. Nitch pointed out that radiation effects on man have been spotlighted in the past few years. She stated that there is no doubt that certain delayed effects are harmful to man but that human genetics are not far enough advanced to give precise answers regarding the damage to reproductive cells at various levels of radiation.

Nitch stated that most information is collected on subjects who have been exposed to high levels of radiation energy. Along these lines the State health department is studying the possible effects resulting from the use of X-rays and fluoroscopy among the patients in State tuberculosis and crippled children's hospitals. Nitch went on to say that for five decades low or moderate energy levels have been used in medical diagnostic radiology and the sum of human benefits derived can never be measured.

Recently, however, some authors have become concerned about the possible hazards from radiation in medical practice and there is some danger of hysteria in a confused public. There are 129,000 X-ray machines in Pennsylvania, 50 percent are used by dentists and the remaining half are owned and operated by medical doctors, osteopaths, chiroprodists, and chiroprac-

tors, of which less than half are operated by radiologists. Of the 13 million fluoroscopic examinations, only half are done by a radiologist, the other half are performed by radiologically untrained medical doctors. Added to this figure are the 5 million radiographs and 1,900,000 fluoroscopic examinations performed annually by osteopaths, chiropractors, and chiropractists.

There is an apparent need for continuous education of professionals and the laity. At the same time, it is essential to have research into the detailed nature and magnitude of these hazards to find out:

1. How much radiation will produce given biological effects?
2. What is the relation of the age of the individual to the dose necessary for any given effect?
3. Are all end results without threshold in their inception?
4. How do the various somatic responses differ in relation to the dose?
5. What is the range of variability of response in any given group of humans?
6. To what extent are radiation responses dependent upon co-factors in the genetic and environmental profile?

Package-type sewage treatment plants are being widely adopted as a solution to waste disposal problems for suburban housing developments, joint schools, shopping centers, and industrial plants not reached by municipal sewerage systems, Arthur F. Lehmann, chief of the sewerage system section in the division of sanitary engineering, declared.

These small treatment plants generally combine a high degree of treatment with a minimum of operation, and their widespread adoption indicates that their cost is not prohibitive, Lehmann stated. "Cost of installing sewers and treatment plants usually is recoverable in the purchase price of houses in a subdivision," he said. "These small plants serve a useful purpose as an intermediate solution until trunk or interceptor sewers can be extended to pick up isolated housing developments," Lehmann added. "Package plants offer one solution to the widespread problems caused by overflowing septic tanks," he said.

The State health department is asking real

estate developers to install sewerage systems instead of septic tanks in suburban developments wherever possible, according to Thomas A. Ford, chief of the suburban development section in the division of sanitation. He told the conference that septic tanks are not suited for use in large areas of the State because of soil conditions. Before new homes are erected, Ford said, developers are being contacted and asked to report on the feasibility of tying in with municipal sewers and sewage treatment plants or constructing small interim plants. He reported that Pennsylvania is the first State to use this feasibility report system.

Habits of food servers are the target of a fresh approach to restaurant sanitation. Hugh C. Sarraf, chief of the food section in the division of sanitation, believes that the restaurant grading system which gives eating places A, B, or C ratings has outlived its usefulness since grading accomplishes only a change in equipment. He plans a study of attitudes and patterns of behavior of employers or employees. Sarraf also asserted his belief that more people suffer from poor management of food in the home than from food contaminated in restaurants.

The food section chief also revealed that State sanitarians are trying to help hospitals control the spread of staphylococcus infection.

"Who killed the fish?" is a question to be answered many times each year by the division of sanitary engineering of the department of health. Marlin E. Wilt, regional sanitary engineer for the north central region, presented a factual account of a fish killing which occurred in 1956. There are three general reasons for a fish killing: natural phenomena over which there is no control, accidents or unforeseen circumstances, and surreptitious discharges of toxins. Most fish killings are accidental or occur because of unforeseen circumstances. In some instances killings can be costly and ecologically significant. As presented by Wilt, the facts are given as the case was investigated.

November 30, 1956: Went to bed, expecting to go to hunting camp the next day.

December 1, 8:48 a.m.: Awakened by call from fish warden that 200,000 fish (trout) were killed at the Benner Springs hatchery. We agreed on sampling program until I got there.

9:35 a.m.: Notified central office to alert chemical laboratory of samples to be delivered.

12:00 noon: Arrived on scene with sample bottles, D.O. kits, and pH comparator.

4:45 p.m.: Completed sampling of stream all the way to source and placed dye in siphon dosing tank and checked flow through the night to ascertain what time pollutant was discharged. Estimated that discharge occurred at 3:00 p.m., Friday, November 30. Possible sources of stream pollution were ammonia from ice skating rink, caustic boiler water, chemicals from laboratories, or radioactive wastes from reactor. Radioactive contaminants showed negative. Met with borough officials, college officials, and collected more samples.

11:00 p.m.: Met with fish biologist.

December 2, 12:10 a.m.: Lab report shows no cyanide. Other tests being made.

4:30 a.m.: Arrived home.

8:30 a.m.: Returned to scene of killing and made more inspections of stream, sewage treatment plants, and interviewed operators. College officials agreed to carry on investigation by

continued sampling. Waited for lab results and got permission to go to hunting camp.

December 3, 10:30 a.m.: Shot a nice spike buck.

1:00 p.m.: Returned to State college, where head of physical plant informed me that all avenues of the investigation were negative except that 104 gallons of supposedly wornout plating solution had been dumped in a college laboratory sink.

December 4: Checked source of dumping with dye to determine time to reach sanitary sewer and treatment plant and interviewed people responsible for the dumping.

December 5: More meetings but no answers. Lab instructed to save old samples.

December 6: More meetings but no answers.

December 7: Lab reports that cyanide was found in original samples as well as soil samples and in the dead fish.

11:00 a.m.: Officials notified of cause.

2:00 p.m.: Press release issued.

Remarks: 50 pounds of chlorine would have effectively destroyed all the hazardous effects of cyanide and saved 200,000 fish.

Reports of the Osteuropa-Institute

Through its Russian Scientific Translation Program, the National Institutes of Health, Public Health Service, will distribute to cooperating libraries, at no charge, selected biomedical publications issued by the Osteuropa-Institute of the Free University of Berlin.

The first publications selected for distribution are "Current Problems of Soviet Medicine" and "Blood Pressure and Subarctic Climate in the Soviet Union." The first of these volumes summarizes, through a search of the pertinent periodical literature, recent developments in such fields as helminthology, psychiatry, oncology, and otorhinolaryngology. The second volume is a compilation of data on the climatic-meteorological susceptibility of blood pressures in the human organism. A study of blood pressure records of 1,203 World War II German prisoners-of-war forms the basis for this treatise.

Oregon's Radiological Health Program

WALTER R. STAHL, M.D., RALPH R. SULLIVAN, M.D., and HAROLD M. ERICKSON, M.D.

This is the first of three articles describing radiological health activities in Oregon, which have emphasized steps to control radiation exposure of the public from diagnostic X-ray procedures. It provides a chronological account, from the first occupational health surveys of static eliminators in 1949 to a 2-year survey of diagnostic X-ray units in 1957-59. Observations concerning the utility of a survey of X-ray units in comparison with immediate registration and adoption of regulations are included. The two other papers will deal further with the survey of X-ray units.

UNDER its broad health powers, the Oregon State Board of Health promulgated its first radiation exposure standards in 1948, using at first a limit of 0.5 r and later of 0.3 rem per week for occupational exposure. In 1949 the board began surveys of polonium static-eliminators and of cobalt-60 and X-ray industrial radiology sources. These activities have continued to date as part of routine occupational health plant surveys.

In 1953 the Atomic Energy Commission began notifying the board of health of all isotope shipments into the State and invited inspection of licensees. Since that date staff members of the board of health have accompanied the AEC inspector on all his visits and have thus become acquainted with each of the 40 isotope users in the State. This cooperative activity has proceeded satisfactorily as a result of close work-

ing relationships with the regional office of AEC in Richland, Wash.

Another early activity, in 1950, was a survey of shoe-fitting fluoroscopes. More than 80 percent of such units were found to be defective, and regulations requiring all units to meet stringent standards were promulgated in 1951. Periodic check of these machines continued until the summer of 1958 when a special regulation of the board of health outlawed them. No significant resistance to this step was encountered; in fact most of the shoe merchants testifying at a board hearing favored it.

Also in 1950 the Oregon Civil Defense Medical Department was created, and a civil defense advisory board was appointed. Beginning in this same year, training courses in radiological monitoring have been conducted for high school teachers and other personnel. Interest in civil defense and the presence of a full-time medical civil defense officer on the board of health staff served to stimulate interest in radiological health. Coordination of the radiological health program with routine civil defense activities has continued to date.

Beginning in 1953 the division of sanitation and engineering of the board of health has collected and analyzed air for radioactivity from local stations in cooperation with the Public Health Service's community air pollution program. After 1956, sampling stations in Portland and 300 miles distant at Klamath Falls continued this work as part of the National Radiation Surveillance Network operated by the Public Health Service. In addition, the sanitary engineering division has conducted modest surveys of radioactivity in air and water and a few special studies on potentially contaminated local water sources.

Dr. Stahl is assistant professor of general sciences, Oregon State College, and Dr. Sullivan is chief, occupational health section, Oregon State Board of Health. Dr. Erickson, former Oregon State health officer, is now deputy director of the California State Department of Public Health.

The director of the division of sanitation and engineering is a member of the Columbia River Advisory Group to the AEC and has worked with a Public Health Service advisory group on Columbia River problems arising from potential contamination by the Hanford Atomic Laboratories in Richland, Wash. Following a special meeting with the AEC in 1957, standard procedures in the event of accident were agreed upon.

Throughout this early period there was frequent contact between the Oregon State Board of Health and the Public Health Service, as the Service expanded its own radiological health activities. A number of Oregon staff members attended short courses dealing with specific aspects of radiological health given by the Service in Cincinnati and elsewhere.

Radiological Health Law

Initial planning for a comprehensive radiological health law in Oregon began in 1955, when it was realized that States would have to assume responsibility for control of health hazards that might result from large-scale industrial application of nuclear energy and isotopes. Preparation of the law was undertaken by the occupational health section with participation of the division of sanitation and engineering and the State health officer.

Early in 1956, a study was made of laws and regulations dealing with radiation in other States. Particular attention was given to the "model" legislation suggested in "Regulation of Radiation Exposure by Legislative Means," prepared by the National Committee on Radiation Protection (1). Valuable conceptual guidance was found in materials published by personnel of the Public Health Service (2, 3) and by others (4, 5). Proposed legislation in other States, Michigan, for example, also was considered (6-9). Good general information has been published since the original planning of the bill (10-12).

It has been the conviction of the Oregon Board of Health from the beginning that radiation exposure of the public is a health problem and a logical responsibility of the health department, rather than of a special commission or other State agency. With this as its major

provision, the first draft of the proposed bill was written in April 1956 and circulated to interested local radiologists, members of the American College of Radiology, and individuals in the National Bureau of Standards, the Public Health Service, and the AEC. Favorable comments and helpful suggestions were received in reply.

In conformance with the model legislation, which was the basis for the Oregon law, the first draft called for registration of all radiation sources. Following a review of the bill by the State medical society, which obtained a specific statement on the draft from the Oregon Radiological Society, this provision was dropped. Initially the radiologists consulted favored registration, but after further discussions they reconsidered their recommendation. The board of health agreed that the requirement was probably not indicated at the outset.

The medical society suggested that a 2-year "study" of the radiological health hazards be made before promulgation of any regulations in Oregon. In retrospect this turned out to be a sound step. By "study" was meant more than a committee review of the expected problem. It meant an actual field survey of a substantial sample of all sources of exposure, including diagnostic X-ray units.

A leading local radiologist provided continuing assistance in the development of the legislation and, later, in the survey of diagnostic X-ray units. Through him, early cooperation was obtained from the medical society and also from the Oregon radiological group. Liaison with the Oregon State Dental Association was established through the efforts of a local radiodontist who had already initiated considerable interest in dental X-ray hazards in Oregon. Support of the proposed legislation was also obtained from a special committee on radiological health appointed by the chairman of the Portland Chamber of Commerce Health Affairs Committee, himself a radiologist, at the time the board of health began work on the bill.

We cannot stress too much the importance of maintaining close working relationships with local professional societies if a radiological health program is to operate smoothly and successfully. This does not mean that all steps will be readily approved or welcomed by them.

but if they are represented in planning and kept fully informed of proposed activities, solutions can often be worked out that are likely to be supported by the professions as a whole. In November 1956 an ad hoc advisory committee composed of advisers mentioned previously plus a representative of industries using radiation devices and the physician in charge of nuclear medical activities at the local medical school was organized to advise the board of health on radiological health matters.

A final draft of the bill was enacted into law in January 1957. The strong support of the professions represented on the advisory committee was a major factor in its acceptance, with only minor revisions and clarifications, by the legislators. Briefly, the Oregon radiation law contains the following provisions.

The State board of health is authorized to promulgate regulations and standards required to control any harmful effects of radiation in Oregon after completing a 2-year study of radiation exposure. All sources of radiation, except certain small quantities of material exempted by the law's definition of "radiation," are covered. Provision is made for enforcing the regulations through court injunctions and penalties, if necessary. The act also requires the State board of health to appoint a radiation advisory committee of five experts.

The Oregon radiation law, it should be noted, does not state specific exposure limits or technical requirements. These are to be included in regulations, thus allowing greater flexibility.

Because of financing problems, appropriation provisions for the proposed program were submitted in a separate bill, which unfortunately did not pass. However, even without this bill, substantial achievements had been realized: the radiological health problem had been recognized in Oregon, a study authorized, and provisions made for establishing standards.

The State board of health appealed to the Surgeon General of the Public Health Service for assistance. In response several consultants from the Division of Radiological Health visited Oregon, and in February 1958 a trained radiological health officer of the Service was assigned to assist with the program. Immediately after the statute became effective on July 1, 1957, the ad hoc advisory committee was ap-

pointed as the official Radiation Advisory Committee specified in the law. Much credit for the success of the radiological health program must go to the members of this committee.

The Survey

It was immediately recognized by the Radiation Advisory Committee and members of the health department that conducting a 2-year study of radiation exposure would be a sufficiently large and technical undertaking that expert assistance would be essential. This would be particularly true for a survey of diagnostic X-ray units since professional acceptance and support would have to be developed before individual cooperation could be obtained. This impression was amply confirmed by experience in the succeeding months.

In early 1958 the newly assigned radiological health officer from the Public Health Service and the director of the occupational health section of the board of health began detailed planning for the survey of diagnostic X-ray units. Using Federal funds, the State provided a single full-time assistant who had attended one of the short courses in radiological health given by the Public Health Service. With National Bureau of Standards Handbook 60, "X-ray Protection," as a basis, field procedures were formulated and trial runs initiated. After refinement, the forms and techniques were discussed with the Radiation Advisory Committee, which suggested a review by a board-certified radiological physicist, who is a specialist engaged by radiologists to check their units. The consultation was of real value technically. It also served to assure the radiologists and other professional groups that our plans were reasonable and supported by the necessary technical competence.

Conferences were then held with biostatisticians of the board of health in regard to choice of sample, and a routine method for conducting the survey was worked out. Dr. Stahl took part in all early field surveys and personally checked most of the physicians' and radiologists' units. The field staff was given special training concerning routine X-ray practices and medical and dental terminology and received detailed advice as to interpretations of

radiation hazards and relative magnitude of various exposures before they conducted surveys without supervision.

Before the fieldwork was started, several meetings were held with representatives of X-ray equipment distributors in the area. Such dealers play an important role in maintaining X-ray equipment. They are well informed on the practical problems of diagnostic radiology and can offer much valuable advice on what will or will not work successfully in practice.

The results of the study confirmed previous impressions that radiation exposure can be materially reduced by use of equipment and techniques recommended by many radiologists. (Results will be presented and discussed in detail in a later paper.) What is perhaps more important, however, the survey allowed us to develop good working relationships with various professional groups. When obtaining data, we offered suggestions on radiation protection equipment and techniques. In other words, although no regulations were in force, the survey effected some of the benefits of a control program because of its educational value. There is considerable evidence that this voluntary approach will produce as good results as, perhaps even better than, would be obtained by compulsory registration and regulation of X-ray equipment alone. A registration program, of course, if properly interpreted to the professions, need not preclude a voluntary survey with its educational benefits.

Regulations

As specified by the Oregon law, regulations can be promulgated by the board of health after completion of the survey in August 1959. As background, we give the following summary of regulations in other States, based on information readily available (6,7,9). Because changes in this field are occurring rapidly, the figures are not precise.

Of the 13 States requiring registration of radiation sources, 6 or 7 specify registration of all diagnostic X-ray units. Thirty-four States have advisory groups on radiation and are presumably considering diagnostic X-ray exposure along with other possible sources. Seven

States have comprehensive radiation codes specifying limits on exposure for all types of personnel, and a number of others have set such limits as part of existing occupational health or other codes. Only New York, Michigan, Pennsylvania, and California have regulations covering the equipment to be used in diagnostic X-ray work. Several States forbid chiropractors and certain others to use X-ray for diagnosis.

The board of health and its advisory committee on radiation are considering various possible regulations. The general outlook is briefly as follows. There is an undeniable need for regulations regarding radioactivity in air and water, transportation of radioactive material, sale of objects containing radium and radioisotopes, and contamination of food. It would seem reasonable to set uniform occupational exposure standards that will include exposure of personnel in medical and other professional offices. Such regulations may not require continuous monitoring but instead specify frequent spot checks to determine average doses.

On the basis of our field experience, regulation of mechanical devices used with X-ray machines does not appear technically feasible or particularly desirable. Only a few of the many steps that can be taken to reduce radiation exposure of patients are amenable to simple regulation. Most require continuing, active cooperation by the user of the unit, which cannot be guaranteed in practice by rules or standards, but must depend on education and understanding of the hazard. Limits on occupational (and nonoccupational) exposure do not automatically assure the use of protective devices.

On the question of compulsory registration of radiation sources, Oregon is cautiously examining the advantages and disadvantages. The most commonly advanced argument for registration is that it provides a complete and up-to-date listing of all radiation-producing units and also provides the opportunity for bringing the accepted standards to the attention of their owners. We do not believe, however, that 100 percent registration can be accomplished without legal action, and such action is incompatible with present circumstances in Oregon. Further, Oregon officials feel that compulsory

registration may engender animosity and make those who refuse to register inaccessible to further contacts.

We have found it possible to locate at least 90 percent of all radiation sources in the State without registration, through the use of professional society listings and the classified telephone directories. Like other States, we are kept informed of shipments of radioactive materials by the AEC and the Radium Corporation of America, and the occupational health program routinely surveys other industrial and some laboratory radiation sources.

Promulgation of uniform occupational exposure standards would probably have widespread effect. Violating these standards, for example, might provide support for legal action in the event of possible late-appearing injuries. Adherence to them, on the other hand, would constitute considerable protection against such claims. The existence of standards would doubtless become widely known among X-ray technicians, labor unions, and others who would encourage adherence to them. Occupational exposure regulations are not likely to be regarded as interference with the normal practice of any of the professions concerned.

Coordination of Activities

In the spring of 1958 a plan for coordination of all radiological health activities of the Oregon Board of Health was formulated. The main goal was to define possible hazards and delineate the exact responsibility of the several sections of the health department in investigating each. A working understanding was developed without difficulty among occupational health, civil defense, and sanitation and engineering programs, which has facilitated solution of many practical problems such as use and location of the single laboratory counter, calibration sources, and other instruments.

In addition, the health department is coordinating its activities with those of other agencies that have an interest in radiological hazards. At present, these include the State Departments of Agriculture, Aeronautics, Education, and Labor; the State Industrial Accident Commission; the State police and the fire marshal; and the Port Authority. Contact will be or

has been established also with Federal agencies: the Public Health Service, the Department of Defense, the Interstate Commerce Commission, and the AEC, for example.

Advisable under any circumstances, such interagency coordination is particularly necessary if the health department is given primary responsibility for radiation health problems arising from all sources. Industrial development, using nuclear energy or radioisotopes, of course, is an entirely different matter and should be separated from surveillance of radiation hazards, we feel, to insure objective appraisal of potential health problems.

Informal personal contacts, as well as meetings of small groups, are effective in achieving the desired coordination. Unwieldy new administrative organizations should be avoided.

Professional education, as already indicated, is basic to a radiological health program. In addition to the work with X-ray technicians, dentists, and physicians in connection with the survey of X-ray units, we have held lectures and demonstrations for X-ray technicians, physicians, veterinarians, radiologists, and others.

Education of the public is also essential. To avoid misunderstanding, however, great care must be taken in framing statements for public use, particularly those dealing with highly technical matters. A statement that is misinterpreted could seriously impede radiation control activities.

Summary

Major accomplishments in the development of a radiological health program in Oregon include enactment of a law giving the board of health broad responsibilities for control of all sources of radiation and for conducting a 2-year survey of diagnostic X-ray units. Close liaison with various State and local professional groups, achieved with the aid of an active Radiation Advisory Committee of outside experts, has proved of great assistance.

Regulations are to be promulgated by the board of health after completion of the survey. An undeniable need is recognized for regulations concerning environmental contamination, occupational exposure, and acci-

dents involving radioisotopes. No decision has been reached concerning uniform registration of sources.

A formal plan clearly specifying responsibilities and areas of activity has been established for coordination of the work of various sections of the health department. Both professional and public education, considered basic in a radiological health program, have received attention.

Institute on Chronic Disease Control

A 2-week institute on chronic disease control will be held June 13-24, 1960, at the University of Michigan School of Public Health. Co-sponsors of the institute are the directors of chronic disease teaching programs of schools of public health, the Association of State and Territorial Chronic Disease Program Directors, the Michigan Department of Health, and the Public Health Service.

Lectures, seminars, and discussions on health promotion, prevention, early detection, multiple screening, home care, institutional care, and rehabilitation, in such chronic diseases as heart disease, cancer, diabetes, glaucoma, and cerebral vascular disease, will be included in the program.

The institute is designed primarily for public health physicians in chronic disease control programs, but selected public health nurse consultants, nutritionists, and health educators who plan and administer such programs at State and local levels also are eligible to attend.

Attendance will be limited and applications for participation must be received not later than May 15, 1960. Additional information may be obtained by writing to the Director of Continued Education, School of Public Health, University of Michigan, Ann Arbor.

An analysis of available data on diet shows little group variation in the consumption of fats and oils between populations of urban and rural areas and between income groups in the United States.

Fat Consumption in the United States

FREDERICK H. EPSTEIN, M.D.

VITAL STATISTICS show wide variation in arteriosclerotic heart disease mortality among different States of the Union (1). Such variations, if real, might be related to differences in dietary habits, particularly with regard to fat consumption. The U.S. Department of Agriculture has published extensive tables on food consumption based on household interviews conducted in the spring of 1955, which permitted testing for differences among the four major regions of the Union (North East, North Central, South, and West), between urban and rural areas, and between income groups (2). Variations in the quantity or types of food consumed among the population segments thus defined would be of help in identifying groups suitable for more detailed epidemiological studies of the relation between nutrition and cardiovascular disease.

This analysis of the U.S. Department of Agriculture data searches for such variations. It was realized, however, that the original survey was intended to serve a quite different purpose, that is, to collect information "for administration of public programs affecting food supply, distribution and consumption; for educational programs to improve food habits, and for private efforts to broaden and improve the

marketing of foods" (2, 3). Data collected for one purpose do not necessarily lend themselves to analysis for another. Yet this study seemed justified in view of the paucity of detailed information on the food habits of subgroups of the general population in the United States and their possible relation to disease patterns, particularly atherosclerosis.

Several publications of the U.S. Department of Agriculture have summarized part of the information called for the survey (4-7). In particular, the average fat consumption in the four major regions, North East, North Central, West, and South, was analyzed in terms of saturated and unsaturated fatty acid content but no breakdowns by degree of urbanization and income were made (5, 7). Our data present a systematic and simultaneous analysis of almost all relevant fat-containing food items in the diet by region, by degree of urbanization, and by income group. Moreover, the data given in the tables published by the U.S. Department of Agriculture refer to average household rather than per capita consumption, regardless of the fact that certain food items are eaten only by a proportion of the population. In this analysis, data are presented for per capita consumption among users only.

Our findings suggest that major overall dietary habits of fat consumption vary remarkably little among different broad segments of the general population within the United States, a significant observation from the point of view

Dr. Epstein is associate professor of epidemiology, School of Public Health, University of Michigan. This study was supported by a grant from the National Heart Institute, Public Health Service.

dents involving radioisotopes. No decision has been reached concerning uniform registration of sources.

A formal plan clearly specifying responsibilities and areas of activity has been established for coordination of the work of various sections of the health department. Both professional and public education, considered basic in a radiological health program, have received attention.

Attendance will be limited and applications for participation must be received not later than May 15, 1960. Additional information may be obtained by writing to the Director of Continued Education, School of Public Health, University of Michigan, Ann Arbor.

Figure 1. Total fat consumption in four regions of the United States

ANNUAL INCOME. In urban areas: Group 1, under \$2,000. Group 2, \$2,000-2,999. Group 3, \$3,000-3,999. Group 4, \$4,000-4,999. Group 5, \$5,000-5,999. Group 6, \$6,000-7,999. Group 7, \$8,000-9,999. Group 8, \$10,000 and over. In rural areas, except in the West: Same as

in urban areas except for group 6 which refers to incomes of \$6,000 and over. In rural areas in the West: Group 1, under \$2,000. Group 2, \$2,000-3,999. Group 3, \$4,000-5,999. Group 4, \$6,000 and over. Incomes not classified denoted by question mark.

the variations inherent in the method of data collection.

In summary, there is a considerable degree of uniformity in average caloric, protein, and fat intake, irrespective of region (North East, North Central, South, or West) or area (urban, rural nonfarm, and farm). However, caloric intake tends to be lower in the two more urban areas in the North East, and there is a distinct tendency for all three variants to show a positive correlation with income in the two more urban areas in the South and West and possibly in the other two regions as well.

Fats and Oils

The "total fats and oils" category includes butter, margarine, shortenings, salad dressings, and salad and cooking oils. Household fat consumption increases with diminishing degrees of urbanization in all four regions (fig. 2). This trend, as well as the higher consumption in the South, reflects household size.

Since differences in average household consumption tend to reflect differences in household size rather than true differences in consumption between groups, only per capita consumption will be discussed. Household data may be obtained from the detailed tabulations. Per capita consumption of fats and oils is strikingly similar in all regions and within comparable areas and income groups, except for a somewhat lower level in the urban North East, where total caloric and total fat consumption are also lower. In each region, except in the West, consumption per person is lowest in the urban and highest in the rural areas.

Baked products, not being primarily fat-containing, have been excluded from this analysis. While the consumption of baked products and prepared foods is known to be higher in urban than rural areas (6), it is unlikely that their inclusion would have materially altered the general picture of fat consumption. Baked goods form but a part of the category of "grain products," a group which, even as a whole, accounts

of epidemiological research into the causes of atherosclerotic diseases.

Methods of Analysis

The tables on "Dietary Levels of Households" were used for the determination of total calorie, fat, and protein consumption (3). Individual food items were analyzed, using the tables on "Food Consumption of Households" (2). These tables provide data on average consumption in households and also the average number of persons per household in different regions and groups. Thus by dividing household consumption by household size, per capita food consumption of the total segment of the population under consideration may be calculated.

A further correction is required for calculating consumption among those actually using the food item in question. This can be accomplished by dividing the average per capita consumption by the percentage of "users," a figure also given in the tables. An error may be introduced by this method since it tacitly assumes that household size is the same among users and non-users, not necessarily a correct assumption. Thus, in Great Britain at least, it has been shown that the number of children in a family, a decisive factor in household size, is more critical than social status in determining food habits (8). In defense of using the correction in question, it may be said that the average household size in the four different areas of comparable urban and rural localities is generally so similar (3 to 4 persons per household) that the assumption of comparable household size among users and non-users may produce no more or possibly even less error than the uncertainties inherent in gathering the basic dietary information, or the inevitable failure to adjust for the varying ages among the household members.

The basic data refer to food consumed rather than food purchased. Nevertheless, there is likely to be some overestimate of intake because of "food waste," a quantity notoriously difficult to gauge. Uncertainty regarding food waste is particularly troublesome in estimating fat intake.

Eighty-eight charts have been prepared. Twelve of these depict the intake of calories,

protein, and fat in the four major regions. The remaining 76 charts pertain to household and per capita consumption of 19 different fat-containing food items. Each chart represents one of the four regions. Each of the 88 charts includes breakdowns into the three degrees of urbanization, urban, rural nonfarm, and rural, and, within these, different income groups.

Calories, Protein, and Fat

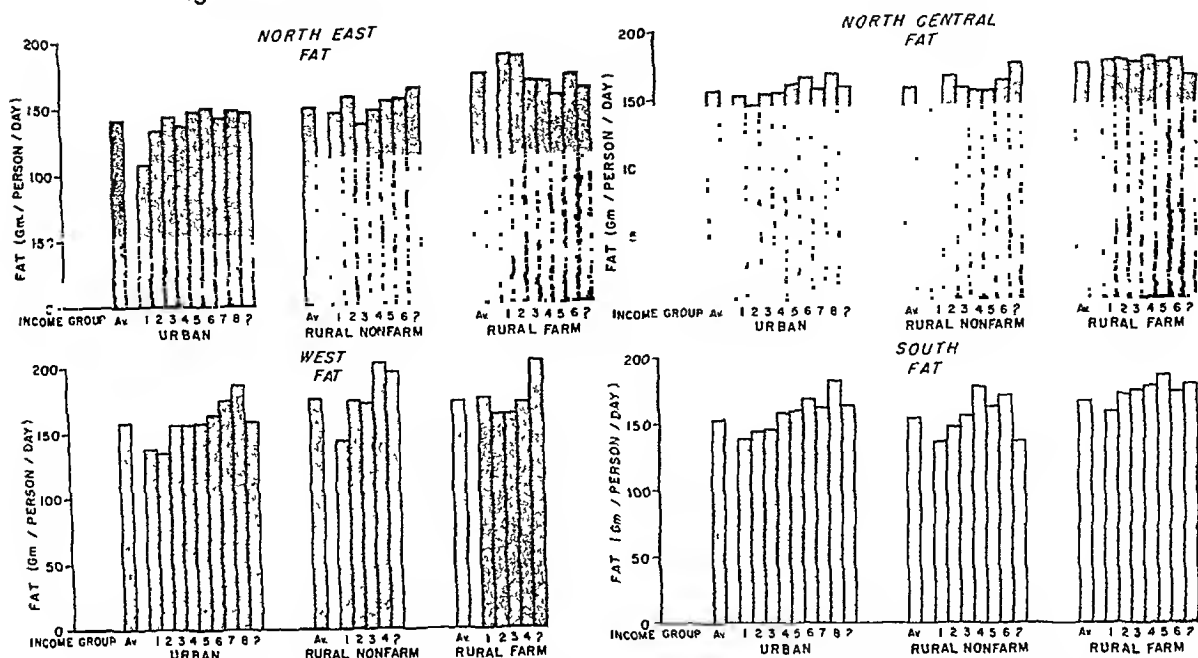

The large number of charts precluded publication in their entirety. Instead, a summary of each set of charts is presented, including some representative diagrams for illustration (figs. 1 and 2). Brief, descriptive annotations of the charts are obtainable from the author upon request.

Average total caloric intake tends to be somewhat lower in the urban and rural nonfarm areas of the North East than in the comparable areas of the three other main regions of the country. There is a general tendency for caloric intake to increase, moving from town to country; intake in the farm areas is uniformly highest, including the North East. There is no discernible association between caloric intake and income level, except for a slight positive correlation in the urban North East and in the urban and rural nonfarm areas of the South and West.

Average protein intake seems to be no different by region or area, except for a somewhat lower intake in urban and rural nonfarm areas of the South. In the same areas in the South and the West, the protein intake tends to rise with income; a less definite but suggestive correlation with income is noted in the two urban areas of the North.

The trends for total fat and protein consumption are similar except that farm consumption usually tends to be higher than urban and rural nonfarm consumption (fig. 1). As in the case of protein, fat intake tends to rise with income in the urban and rural nonfarm areas in the South and West, income group 1 denoting the lowest and income group 8 the highest level. It is difficult to decide from inspection of the graphs whether any of the less obvious differences between income groups are significant statistically or nutritionally, taking into account

Figure 1. Total fat consumption in four regions of the United States

ANNUAL INCOME. In urban areas: Group 1, under \$2,000. Group 2, \$2,000-2,999. Group 3, \$3,000-3,999. Group 4, \$4,000-4,999. Group 5, \$5,000-5,999. Group 6, \$6,000-7,999. Group 7, \$8,000-9,999. Group 8, \$10,000 and over. In rural areas, except in the West: Same as

in urban areas except for group 6 which refers to incomes of \$6,000 and over. In rural areas in the West: Group 1, under \$2,000. Group 2, \$2,000-3,999. Group 3, \$4,000-5,999. Group 4, \$6,000 and over. Incomes not classified denoted by question mark.

the variations inherent in the method of data collection.

In summary, there is a considerable degree of uniformity in average caloric, protein, and fat intake, irrespective of region (North East, North Central, South, or West) or area (urban, rural nonfarm, and farm). However, caloric intake tends to be lower in the two more urban areas in the North East, and there is a distinct tendency for all three variants to show a positive correlation with income in the two more urban areas in the South and West and possibly in the other two regions as well.

Fats and Oils

The "total fats and oils" category includes butter, margarine, shortenings, salad dressings, and salad and cooking oils. Household fat consumption increases with diminishing degrees of urbanization in all four regions (fig. 2). This trend, as well as the higher consumption in the South, reflects household size.

Since differences in average household consumption tend to reflect differences in household size rather than true differences in consumption between groups, only per capita consumption will be discussed. Household data may be obtained from the detailed tabulations. Per capita consumption of fats and oils is strikingly similar in all regions and within comparable areas and income groups, except for a somewhat lower level in the urban North East, where total caloric and total fat consumption are also lower. In each region, except in the West, consumption per person is lowest in the urban and highest in the rural areas.

Baked products, not being primarily fat-containing, have been excluded from this analysis. While the consumption of baked products and prepared foods is known to be higher in urban than rural areas (6), it is unlikely that their inclusion would have materially altered the general picture of fat consumption. Baked goods form but a part of the category of "grain products," a group which, even as a whole, accounts

Figure 2. Separated fat and oil consumption in four regions of the United States

NOTE: For annual income of the groups see figure 1.

for no more than 5 to 7 percent of the calories derived from fat in the different regions and areas (3). It is not implied that baked products are an unimportant source of fat or calories for some people or groups.

It is clear that the total consumption of separated fats is high, regardless of region, degree of urbanization, and income. The types of separated fats contributing to this total picture might be suspected to differ appreciably among the various population groups, but further analysis gives little support to this hypothesis. When the consumption levels of butter, margarine, shortenings (lard and nonlard), salad dressings, and salad and cooking oils are charted individually, no striking differences among regions, areas, or income levels emerge. More-

over, since the proportion of users of these various types of separated fats is reasonably similar from one region, area, or income level to the next, these observations rule out major inter-group differences in the food patterns under discussion. Yet some differences must exist since we must assume that the non-users of one particular type of fat substitute another, for example, vegetable shortening for lard, if we are to account for the similarity in total fat and oil consumption among different subgroups. The basic tabulations do not provide the breakdowns necessary for such an analysis, which was beyond the scope of the original purposes of the survey as explained. Nevertheless, significant group variations in this regard may well exist. Thus, although relatively few households use

salad and cooking oils, consumption tends to be high among those who do, presumably at the expense of the more saturated forms of fat.

Dairy Products

Detailed tabulations have been made for milk (fresh fluid and evaporated), cream, ice cream and ice milk, cheese, and eggs. In general, the findings are similar to those for separated fats. Little variation in consumption level has been encountered among the users in the different regions, areas, and income groups. Likewise, for each given dairy product, the percentage of users tends to be comparable from one population subgroup to the next. Rural areas in general and the South are exceptions. Consumption is higher in farm districts and lower in the southern States. Within the dairy products group, there is less room for substitutions than in the "fats and oils" category and there is even firmer ground for stating that there are no major intergroup differences in consumption.

Meat, Poultry, and Fish

As in the case of fats and oils and dairy products, the economic leveling process has tended to equalize differences in meat, poultry, and fish consumption. Exceptions are a lower meat consumption in the South, at all degrees of urbanization, and a slight positive association between meat consumption and income. Also, the proportion of households using fish is higher in the North East. The present findings are not in accord with the statement that meat is of lesser importance in rural diets (5). The data in support of this claim are based on the total category of "meat, poultry, and fish" and, not being expressed as per capita consumption of users, can be explained by the fact that the proportion of users of poultry and fish is higher in urban than rural areas.

Comments and Recommendations

It would seem permissible to conclude from these data that selected income groups in certain regions and areas of the United States do not appear to offer themselves as units for more detailed study of the relationship between fat

intake and coronary heart disease. Yet, it is likely that there are more narrowly defined cultural and religious subgroups within the United States differing sufficiently in dietary habits to permit a study of the relationships between diet and disease in this country which might be more easily interpreted than certain international comparisons.

There is also a need for concurrent clinical and dietary studies among populations or representative population samples, using methods of dietary history taking of adequate validity and reliability, in order to delineate differences in dietary habits between individuals within the same group rather than searching for differences between groups. In this light, the original interview records collected in the survey by the U.S. Department of Agriculture may still offer opportunity for more detailed scrutiny.

Originally it was hoped that information on the type and amount of fat-containing foodstuffs would provide an indirect measure of the degree of saturation of fats in the diet of a given group. It seemed too difficult, however, to gain a consistent picture of dietary fatty acids content by reconstructing the contributions of individual food items. Stiebeling has analyzed the survey data on fats in terms of saturated, oleic, and linoleic acid content in the four regions but provided no further breakdown by degree of urbanization or income, nor did she correct for the effect of non-usage (7). This analysis suggested a somewhat higher ratio of unsaturated to saturated fatty acid in the South; the other three regions showed no appreciable dissimilarities in this regard.

It is not possible to extrapolate these findings to the more detailed ramifications of the populations into the areas and income groups discussed here. If the general conclusion is correct that no major differences in the consumption of fat-containing foods exist between the population segments considered, the same conclusion would generally apply to the constituent fatty acids.

Summary

An analysis, based on the household food consumption survey made by the U.S. Depart-

ment of Agriculture in the spring of 1955, of the consumption of calories, protein, and fat, and the major fat-containing foods, has been made. The consumption of "fats and oils," "dairy products," and "meat and fish" has been broken down into 19 different food items. For each of these, data are presented on the proportion of users of the various foods, their consumption level among the households using them, and the per capita consumption by the users. These data are further broken down by the four major regions of the United States, degree of urbanization, and income level. This report, differing in aim from others published, is based on calculations including only households actually using the food item rather than averages for the total group regardless of the proportion of users.

Epidemiological studies into the relationship between fat intake and atherosclerosis aim at delineating population segments differing in fat intake. The present analysis was undertaken in the hope that the extensive and detailed fragmentation of the total population by region, area, income, and proportion of users might identify subgroups exposed to possible preferential risk by a high intake of certain fats. Allowing for methodological difficulties, no such susceptible population subgroups could be shown to exist in the United States in terms of the particular breakdowns made. The feasibility of epidemiological studies of the kind envisaged within the United States would seem to depend, therefore, on identifying intra-group differences between individual members of the community rather than intergroup differences between broadly defined regional or socioeconomic population segments.

DOCUMENTATION NOTE

The complete set of 88 charts and the tables from which the charts were drawn, covering variations in

the fat and oil consumption among the population segments defined by the U.S. Department of Agriculture survey of diet in the United States by household interview, have been deposited as document No. 6142 with the American Documentation Institute Auxiliary Publications Project, Photoduplication Service, Library of Congress, Washington 25, D.C. A photoprint may be obtained by remitting \$25; a 35-mm. microfilm copy by remitting \$7. Cite document number. Advance payment is required. Make checks or money orders payable to Chief, Photoduplication Service, Library of Congress.

Ambulance Service

in Seattle

S. P. LEHMAN, M.D., M.P.H., and K. H. HOLLINGSWORTH, B.S.

Survey of Service

IN 1953, Seattle, Wash., began to appraise the King County emergency ambulance service on the basis of costs, efficiency, and in relation to traffic hazards. Traffic casualties were singled out since they represent more than two-fifths of the total accidental deaths in the United States and are the main recipients of emergency ambulance service (1).

Since 1892, Seattle, Wash., has recognized the importance of ambulance service for its residents. Back in those days, the ambulance was a wagon used to carry patients to the small-pox isolation hospital, known as the "suspect house." Today 20 well-equipped ambulances are supplied by four independent privately

owned companies to answer emergency calls in the city.

A supplementary survey was conducted in July 1958 to compare the ambulance service in Seattle with other cities. A questionnaire prepared by the Seattle-King County Health Department was distributed to the 113 cities in the United States and western Canada whose estimated population numbered over 100,000. Ninety-nine local health departments, or 88 percent, returned the questionnaires, and their answers supplied the following information:

- Thirty cities rely solely on city, county, or State-owned equipment to supply ambulance service. Further communication with these cities revealed that their equipment varies from the typical ambulance to station wagons, vans, and specially equipped police cars.

- Thirteen cities use private companies under contract at a fixed annual fee as their exclusive suppliers of ambulance service.

- Thirty-two cities use privately owned ambulances without any formal contract arrangement. In some cases, this service costs the city

Dr. Lehman is director of public health in Seattle. Mr. Hollingsworth is a senior medical student serving in the division of health education of the Seattle-King County Department of Public Health.

nothing, since only private companies operate, with no official city intervention or contract. In others, the city reimburses the private ambulance owner on a per call basis.

• Twenty-three cities make use of several types of ambulance service, supplementing municipally owned vehicles with privately owned or contracted ambulances.

The annual cost of ambulance service does not seem to correlate with population, number of vehicles, calls per year, or type of service used. In many cases, cost estimates are unavailable, especially when the ambulance service is a division of the police department with patrol cars and personnel used for both emergency calls and police business.

In most cities, the police work closely with ambulance services. In 60 cities, dispatching is done by the police department. The role of the police dispatcher is an important one. A patrol car is usually called to the scene of an emergency before an ambulance, whether the emergency is a traffic accident, street fight, or other unusual disturbance. The patrolman ascertains the need for an ambulance, orders the dispatcher to send one, and attests to the need for speed and the use of a siren. The fire department dispatches ambulances in 7 cities, and 23 cities rely on a telephone call to start the emergency vehicle on its way.

Growth

Seattle's ambulance service has improved with experience and growth. In 1899, the board of health asked the city council to establish an ambulance service officially (2, 3).

Eighteen years later, in 1917, the annual re-

port of the department of health carried the following paragraph:

"The ambulance service has been very efficient during the past year. We have one well-equipped ambulance that answers any emergency call to any part of the city. There is only one cot in the ambulance but, when necessary, two patients can be transferred. There is in the ambulance, a lung motor, emergency kit with all necessary instruments, medicine and dressings for any emergency case, and also padded emergency splints for fractures. They can be temporarily applied for the transportation. The ambulance is driven by the police department and kept in the police garage. With the cooperation of the police department, a stretcher is carried on the patrol car [which accompanies the ambulance] and a good many calls are made by the patrol and the patient transferred very comfortably. When the ambulance is out and a second emergency call comes, a doctor always accompanies the patrol" (4).

On January 1, 1925, the city-operated ambulance service was changed to a contract system with a "well-established and reliable firm,"

Table 2. Cost to the city of emergency ambulance service, Seattle, Wash., 1953-58

Year	Calls processed	Calls paid by city	Per cent	Cost per call	Total cost

¹ From 34 to 73 patients refused a city-dispatched ambulance or used other transportation, but in all these cases the city was still under agreement to pay for the call.

Shepard Ambulance Service, at a saving of about \$3,000 per year. The contract called for supplying emergency ambulances from a central and north-end location, and, in addition, an ambulance from 7 p.m. to 7 a.m. at the Public Safety Building. Interns at the City Emergency Hospital, opened in 1909, rode the vehicle until just before World War II when, because of extreme doctor shortage, it became necessary to staff the ambulances with orderlies. For this contract service, Seattle paid \$1,000 per month in 1944, and \$1,100 monthly in 1945.

The contract system with Shepard Ambulance Service ended in the summer of 1947. On July 1 of that year, three ambulance firms were engaged, to be reimbursed on a per call basis for uncollectible emergency runs. A Shepard ambulance continued to operate at night from the Public Safety Building.

The current system is essentially the same as the one established in 1947. The city neither owns nor operates any ambulances.

Method of Operation

The four independent, privately owned companies who supply the 20 ambulances which answer Seattle's emergency calls have established, by their own agreement, six zones within the city limits. Each company or branch office of a company handles emergency calls in one assigned zone. All emergency calls are channeled by two-way radio to a dispatcher, on duty 24 hours a day at City Emergency Hospital, now the jail infirmary since the opening of the King County Hospital in 1931. The dispatcher calls the appropriate company for the zone in which the accident occurs. If the company has no equipment available, the dis-

patcher calls for an ambulance from a neighboring zone.

The police department is Seattle's main source of calls to the central dispatcher (table 1). All calls are accepted, however, with the exception of calls for service resulting from accidents and illness occurring in industrial establishments, for nonemergency service, and for patients, other than traffic casualties, who are recipients of public welfare. Industrial firms must make their own arrangements for emergency service. Nonemergency service is not considered a city responsibility and, in the same way, persons receiving public welfare are considered private cases since a request from a physician must be made to the welfare department before ambulance service can be authorized.

Although the city's contract with the companies supplying ambulance service does not contain specific regulations, certain rules governing the service have been agreed upon by the participants. They are:

1. The participating companies must maintain and keep in service at least two ambulances at all times.

2. The crew of an ambulance on call must consist of a driver and an assistant, one of whom must hold a Red Cross first aid certificate or other certificate of equal standing or have had enough actual experience to compensate for a certificate.

3. The following accessories shall be carried in each ambulance: invalid couch-type bed on wheels; stretcher for second patient on floor or

hanger; bandages, tourniquets, and splints; oxygen; and clean linen and blankets for two patients.

4. Communication procedures require that only company offices which maintain two-way radio dispatch service or the central dispatch office contact ambulance drivers. Under no circumstances may one company transfer calls to another; rerouting is to be handled exclusively by central dispatch. And all calls must be handled promptly.

5. Participating companies must carry insurance in the amounts of \$50,000 and \$100,000 for public liability and \$10,000 for property damage. The required insurance coverage must be certified in writing to the health department by the insurance carrier, who must also stipulate the amount of insurance coverage for each accident and each individual, and agree to notify the department immediately of policy cancellation or change.

6. Companies are to collect payment for calls within 90 days, and prevailing rates are to be charged. The city will reimburse the companies for unpaid-for calls at the end of the 90-day period. Rates to be charged the city are established by the health department each year. When two persons are carried, the company will be paid by the city for only one person. When collection is made from one person in instances where two persons were carried, the company shall not collect from the city for the second person.

7. Reasons for curtailing or discontinuing the services of an ambulance company are: re-

NOTE: For some patients more than one condition was reported.

ceiving and answering calls from other than regular channels; tuning in on police calls; poor condition of ambulance, equipment, and supplies; failure to supply trained crew; unnecessary delay in answering calls; and failure to carry and keep in force proper amount of insurance.

8. Rulings of the director of public health shall be final.

Table 2 shows the number of emergency ambulance requests since 1953 and the number of calls paid for by the city. The city bears the expense of between 59 and 65 percent of all emergency calls dispatched by the City Emergency Hospital. The cost in 1958 was \$26,976.

The cost of the present program, however, is less expensive than a city owned and operated service would be. A new Cadillac Superior ambulance costs about \$10,000, f.o.b. factory, and to equip the city with a fleet comparable to the one now available would cost about \$200,000. Maintenance expense and salaries for drivers and attendants would swell this amount. With the present system, the city cooperates with private enterprise instead of competing with it, has satisfactory ambulance service at relatively low cost, and is supplied with a combined fleet of 20 vehicles at strategic locations.

In the past 3 years, approximately 75 percent of all emergency calls were routed to King

County Hospital, with less than 21 percent going to private institutions (table 3).

Table 4 shows the frequency of calls at 3-hour intervals round-the-clock. Tables 5 and 6 reveal the ages of patients and the reasons given for requiring ambulance service.

Traffic Demands

A MAJOR ISSUE in supplying any city with emergency transportation for ill or injured patients is the need for sirens and flashing red lights to permit ambulances the right-of-way. Speed beyond posted limits is another facet of the same issue. Both medical and non-medical agencies are concerned.

In Seattle, the law is clear regarding attainment of the right-of-way. Both the ordinances of the city and the laws of the State of Washington demand that ambulances and other emergency vehicles give "audible signal by siren, exhaust whistle, or bell."

Proponents of noise abatement believe that the reduction or elimination of the use of the ambulance siren will aid in the achievement of their ultimate objective. Two courses of action may be taken to accomplish this purpose: repeal of existing laws which give ambulances the

opportunity to gain the right-of-way; or imposition of strict limitations on ambulance movement, listing certain situations in which the right-of-way should be granted. Consideration must be given to the exercise of sound medical judgment by a well-trained medical person in the second course mentioned, a person with more training than the average ambulance attendant.

In order to gain the right-of-way, a certain amount of noise must be created. The earliest ordinance prohibiting unnecessary noise was enacted in Stamford, Conn., in 1926, but sections of city ordinances have dealt with the subject since 1891 (5). In a 1930 study by the New York Noise Abatement Council, fire, police, and ambulance sirens constituted 4.12 percent of 11,068 complaints of noise in a city with a network of elevated, subway, and trolley cars.

It has also been mentioned that ambulance sirens and the warning devices of the police and fire departments may be confused with a civil defense alert. In 1950, New York City ambulance sirens were removed specifically for this reason, but a year later the order was rescinded.

Many people believe that, in addition to creating undesirable noise by the use of sirens, the right-of-way privilege given to emergency ambulances increases accidents at intersections. In Seattle, permission is given to ambulances to disregard stop signs and traffic signals if they give the "audible signal" specified in State and local laws.

Although the total number is not available, the Seattle police department has records of seven injuries and six instances of property damage from traffic accidents involving ambulances in 1958. In 1957, there were five injuries and nine instances of property damage. The four participating ambulance companies report a collective total of nine traffic accidents in the past 3 years. None of these was fatal. It is reported that six of the accidents occurred at an intersection while the ambulance was operating with siren and red lights. Two operators said that the accidents were the result of "too little siren" and could have been avoided if the siren had been blown louder.

A study was undertaken in New York City to prove that revoking right-of-way privileges

would reduce traffic accidents involving ambulances (6). In 1949-50, there was 1 accident in every 972 calls when sirens were in use and ambulance drivers were permitted to ignore traffic regulations. When sirens were removed in 1950-51 due to possible confusion with civil defense air raid signals, the ratio climbed to 1 accident in 715 calls, with the drivers still being permitted to ignore traffic regulations. In May 1953, the order was rescinded, sirens were restored, and right-of-way privileges remained in force. From June through September of that year, the ratio rose to 1 accident in 690 calls. The study began in October and continued through December 1953, a period of 3 months during which time all ambulances in the city adhered to traffic regulations and operated without sirens. Accidents declined 52 percent, or to 1 in 1,460 calls. During 1953-54, there was a further decline to 1 accident in 2,380 calls. Allegedly, denial of right-of-way privileges did not decrease the efficiency of emergency ambulance service in New York City.

In Seattle, the four operating ambulance companies are aware of the controversy on right-of-way privileges. Sirens are used in answering a call only when specified by the physician or city dispatcher. In transporting a patient to the hospital, use of red lights and siren is directed by the police, the attending physician, or, lacking these, by the ambulance attendant. The companies state that right-of-way is refused unless a siren and red lights are used and, without right-of-way privileges, a delay of from 30 to 60 minutes may result. In a peak-hour traffic situation, the delay may be even longer.

Seattle's experience with the "speeding ambulance" is limited. Three of the four operating companies require police escort before operators may exceed city speed limits. These companies believe the extra speed is not necessary if the ambulances are allowed free passage along thoroughfares and are given right-of-way through traffic signals and intersections.

City Ordinances

In replying to a questionnaire on emergency ambulance service prepared by the Seattle

health department in July 1958 and distributed to 113 cities in the United States and western Canada with an estimated population of over 100,000, 30 cities supplied copies of local ordinances governing ambulance operation. These ordinances primarily govern the licensing and control of ambulance operators, but it is apparent that many traffic regulations are applied in an attempt to reduce accidents involving ambulances on call.

No statistically accurate or valid appraisal of traffic laws regulating emergency ambulance service is possible from an evaluation of only 30 local ordinances. But it was noted that some cities had no restrictions on speed of operation while others limited ambulances to a speed 10 miles per hour over the posted limits.

Kansas City, Mo., conducted a study in 1954 of traffic regulations governing ambulances in 54 cities, located in 29 States. From 52 of the 54 cities, it was learned that 26 required ambulances to observe the same speed limits as other passenger vehicles. Thirteen cities required a speed consistent with safety, five specified no speed limit, and three limited ambulances to a maximum speed of 40 miles per hour. Forty of 49 cities did not permit ambulances to run red lights and stop signs, 16 allowed them to ignore such regulations in an emergency. Twelve cities allowed the right-of-way privilege if an audible warning or red lights were used, 10 if the vehicles slowed down at intersections, and 9 if the ambulance was operated "under safety conditions" (7).

It has been noted by one observer that an ambulance traveling 30 miles per hour takes 10 minutes to go 5 miles, yet to arrive at its destination 5 minutes earlier the vehicle would have to travel at double this speed or 60 miles per hour over the same course. A study conducted by Curry at Hurley Hospital, Flint, Mich., of 2,500 consecutive ambulance runs failed to show that 5 minutes would have influenced the course of a single injury (8). It was found that haste was unnecessary in 98.2 percent of the cases: they could have been transported according to traffic regulations. In 1.8 percent, expeditious handling was necessary, but the speeding ambulance could have increased injuries. In only one case was haste necessary to save life. Curry concluded that

ambulances should observe local speed laws, should use sirens, and should have the right-of-way.

Young, in his 238-page book entitled "Transportation of the Injured," states, in a chapter on ambulance safety, that "certainly the siren as an emergency warning device is here to stay. Additional accidents and perhaps even fatal delay could result in urgent cases without such a device. But indiscriminate use of a siren should be avoided, and, even when using it, adherence to normal traffic regulations is the safest policy" (9). Young further states, "From the medical standpoint, there are few emergencies that require speeding to a hospital if first aid is properly rendered on-the-spot."

Driver Training

THE AMBULANCE driver and attendant are initially responsible for the care of casualties. It is important, therefore, that their training be commensurate with their responsibility.

With the limited resource of a first aid certificate or its equivalent in experience, Seattle crews are called upon to care for the patient at the accident scene and en route to the hospital. And the driver may be called upon to decide the speed he will use, either a slow cautious trip at the imposed speed limits and obeying traffic signals, a journey within the speed limits but using the siren and red lights, or a trip of maximum swiftness making full use of privileges of right-of-way and right to exceed the speed limit.

After interviews, it has been suggested that ambulance drivers and attendants in Seattle are not sufficiently trained to make such decisions and prefer to be directed by physicians or police officers. But it is readily apparent that policemen are no better prepared to judge such situations than ambulance crews.

More advanced training of ambulance attendants has been advocated by many officials. Perhaps the most vocal in expressing this view is Dr. George J. Curry, chairman of both the Subcommittee on Transportation of the In-

jured and the Subcommittee for Regional Committees on Trauma of the American College of Surgeons. Curry has published several provocative papers on the emergency care of the injured (8, 10-14) and in each, he has stressed the need for thorough and continual education of ambulance attendants.

An educational program was begun in Flint, Mich., in 1949, with the American College of Surgeons arranging a series of lectures and demonstrations. Expeditious and standardized handling of common injuries was discussed. The educational program was motivated by amendment of local ordinances governing the qualifications of ambulance attendants and regulating equipment to be used in first aid treatment, providing penalties for violations. Ambulance attendants participating in the program were each awarded a certificate of fitness which required renewal annually (8).

A general community plan for action by Curry suggests:

1. Adoption of a city ordinance requiring certificates of proficiency for ambulance attendants.

2. Educational programs for ambulance attendants under the sponsorship of the county medical society, the Regional Committee on Trauma of the American College of Surgeons, or the hospital staff organizations. Such programs can be arranged either directly by the sponsoring groups or through the Red Cross under the sponsorship of specialized organizations. Instruction can be given by physicians in training as residents in local hospitals. In communities lacking hospital house staffs or a hospital, young physicians in the area could serve.

3. A receiving department chart of cases, recording the quality of transportation.

4. Biannual inspection of all ambulance equipment.

5. A well-organized emergency receiving department and efficient organization of hospital care.

6. Delegation of the entire problem to willing workers.

Young devoted one-half of his book, "Transportation of the Injured," to first aid and the ambulance attendant (9). Young believes that the duties of the dispatcher are by no means

unimportant, saying "all calls for an emergency ambulance are urgent until proven otherwise. The urgency of the request should be ascertained by the dispatcher, who should always find out as much as possible about the emergency before sending the ambulance. Those assigned to dispatch emergency ambulances should have first aid training; they can then give essential, lifesaving information to the caller. This practice is soundly recommended. In addition, the dispatcher should ask that someone be available at the scene to assist in locating the injured person quickly."

Seattle's medical community has taken a keen interest in its emergency ambulance program, particularly in speeding and the use of sirens. Dr. Quin B. DeMarsh, president of the King County Medical Society, is currently a member of a surveillance committee studying safety and use of sirens in gaining right-of-way in traffic in the city and other municipalities of 100,000 population. Spontaneous interest by physicians has been augmented by inquiries from the Regional Committee on Trauma of the American College of Surgeons and by community efforts in traffic safety such as the Seattle-King County Safety Council.

DeMarsh has suggested that if the solution

for excessive speed and indiscriminate use of sirens is not found through legal curtailment, an intensive educational program for ambulance drivers and attendants may be the answer. It is apparent that regular surveillance of emergency calls should be accomplished in this community, if the present ambulance system is continued. Both educational and disciplinary measures may be needed to correct the abuses reported in specific cases. Public authorities should take an active role in correcting irregular practices.

Summary

Emergency ambulance service in Seattle has progressed since 1892 from one wagon to a fleet of 20 well-equipped ambulances supplied by four privately owned companies. The city contracts for this service, agreeing to pay for each call remaining unpaid 90 days after the emergency.

The Seattle-King County Department of Health surveyed ambulance service in Seattle in 1953 and in 113 cities in the United States and western Canada with a population of 100,000 in 1958. The current system of operation was influenced by these survey findings.

Analyses of emergency calls in Seattle by source, cost, disposition, time, age of patients, and cause of emergency indicate that police report most casualties; costs per call and total costs have risen with population growth; the majority of all patients are taken to a hospital; the most frequent hours for emergencies are from 3 p.m. to 6 p.m.; persons between 51 and 60 years of age use ambulance service the most; and either traffic accidents or unknown causes are given as the reason in about one-third of the emergencies.

Traffic regulation of ambulances in emergencies is controversial. State and local laws require use of an audible signal to gain right-of-way privileges in Seattle. Studies on speed and noise abatement in other localities have established that speed of delivery of the patient to the hospital rarely has important implications in recovery. Adherence to normal traffic

regulations is advocated by some authorities. Emergency ambulances in New York City, operating without sirens and obeying all traffic regulations, reduced accidents involving these vehicles 52 per cent during a 3-month period in 1953-54.

Advance training of ambulance drivers is presented as a possible solution to problems of ambulance operation. It is suggested that education under the guidance of experienced physicians and other professional personnel in the community will promote the exercise of better judgment by ambulance attendants.

Malaria and Opium Control in Iran

A GLANCE at two major health developments in Iran, achieved in little more than a decade, illustrates the dramatic contributions health workers have made to the well-being of a people.

Iran is one of the many countries with shortages of transportation, communication, industry, equipment, trained personnel, and administrative organization to overcome in its coordinated development. In addition, until 1950, malaria and opium addiction prevented a large proportion of its population from functioning effectively.

Malaria

Despite the lack of national statistics, one could see that large numbers of workers were

suffering attacks of malaria during the growing season. For example, along the Caspian Sea in the north adequate rainfall should have made the land particularly productive. But throughout history malaria had caused it to be known as the "poisonous region."

DDT spraying commenced in 1947 with the first demonstration programs supported by the Near East Foundation and the United Nations. They showed that the transmission of malaria could be controlled rapidly by spraying the insecticide on the walls where *Anopheles* mosquitoes, engorged with malarious blood, rested.

In 1950 the Iranian Seven Year Plan Organization began a national program of malaria control. The U.S. Technical Cooperation Administration (now the U.S. Operations

A malaria control team from the Iranian Ministry of Health crosses a footbridge near the Caspian Sea. The U.S. International Cooperation Administration supplied sprayers and DDT for such teams.

Fields of opium poppies, once conspicuous near every village in central and southern Iran, had disappeared by 1956. Strictly enforced laws forbid cultivation of the plant.

Mission, International Cooperation Administration) contributed insecticide, technical guidance, and administrative support. The World Health Organization supplied malarialogists, entomologists, and technical grants to further scientific guidance. Despite difficulties brought on by the oil crisis and the political pressures of the once strong Tudeh (Communist) Party, the antimalaria work continued to expand. The campaign has been described in detail (E. E. Palmquist and F. F. Aldridge: *Malaria control in Iran*. *Pub. Health Rep.* 69: 976-981, October 1954).

The progress against malaria can be gauged. In the Caspian area the spleen indexes of village children have dropped from 95 to an irreducible 2 percent. Formerly, every clinic there saw hundreds of cases each year; now only sporadic cases are confirmed.

Throughout much of the plateau which comprises most of the country, malarimetric indexes have fallen dramatically. Malaria still exists in Iran, especially in the southern part of the Iranian plateau. But antimalaria cam-

paign workers are concentrating on eliminating the residual reservoir so that the disease can be eradicated in Iran. The work is now supported predominantly by income from Iranian oil and is being administered entirely by Iranians.

Opium

To the casual observer, the most obvious indication of the importance of opium in Iran was the large amount of precious agricultural land devoted to the opium poppy. Of course, not all of this easily transportable product was used in Iran, but it is safe to assume that only a small fraction was turned to legitimate medicinal uses.

The number of addicts was not known, but it was apparent that the narcotic was in fairly common use. While it is true that the surroundings appear less harsh under the influence of opium, the loss of vitality and strength, diminished sense of responsibility, the general inertia, and the expense generally overshadow any benefits conceivable to users. They become dulled and wasted.

By 1956, the opium poppy, previously grown near every village in central and southern Iran, had disappeared. Effective legislation forbidding its cultivation had been hammered through. With the firm support of the Shah and some exemplary penalties, the law has been strictly enforced.

Iran has accomplished a great deal through its own efforts to combat addiction. The public health education division of the Public Health Cooperative Organization (a former administrative pooling of Iranian and United States funds, equipment, supplies, and technicians) contributed to widespread education and publicity through talks, posters, and other information media. Medical, narcotics, and laboratory advisers from ICA and WHO worked with Iran's limited treatment facilities to ease the turmoil which follows suppression of the availability and use of the drug. Drugs to be used temporarily during withdrawal were supplied. An ICA hospital administration consultant helped to expand and reorganize hospital facilities to care for those severely affected by withdrawal.

Enforcement officers for antinarcotics work were trained in a school started with the help of ICA, and scientists, under UN grants, were trained abroad in laboratory techniques for detecting usage. Contact with neighboring countries on the narcotics problem has been fostered by the UN and the CENTO Pact. Agricultural advisers of ICA and the Food and Agriculture Organization helped to supply new crops to fill the gap created by suppression of cultivation and marketing of the product.

The cost of opium has increased to 40 times its 1956 price, out of reach of most users, and the

number of users has been reduced by at least two-thirds. Villagers, dulled for decades, have given up opium and turned to the production of crops and flocks badly needed to support the development of the nation. The effect of Iran's achievement on the international traffic in illicit drugs alone deserves worldwide interest, assistance, and cooperation.

Other Changes

International teamwork has led to other achievements in Iran. To mention a few—the newly emphasized concept of preventing disease has resulted in 12 million vaccinations; typhus outbreaks have been cut short by DDT dusting; women are experiencing a challenging liberation as nursing becomes a respected and useful profession; a widespread health education program is reaching the people; basic public health laboratory methods are being adopted; the largest city in the world without a sanitary water distribution system now has one; and rural sanitation workers are being trained to work on the environmental factors important to the villagers' health.

In these achievements no one worked alone, everyone worked together toward similar goals. Iranians worked with the Near East Foundation, ICA, WHO, UNICEF, Rockefeller Foundation, and others inside and outside the country. Together they formed a team which caused a country to change for the better.

—FRANZ W. ROSA, M.D., M.P.H., *now in Lahore with the U.S. Operations Mission to Pakistan, was formerly public health physician with the U.S. Operations Mission to Iran.*

Control of Staphylococcal Food Poisoning

BENJAMIN E. HODGE, M.D.

STAPHYLOCOCCAL food poisoning is overwhelmingly the most prevalent of food-borne infections in the United States. The need for improved methods of controlling the disease is indicated by the number of outbreaks reported in the annual summaries of disease outbreaks, which show little evidence of decrease in incidence (1-4).

Factors responsible for outbreaks of staphylococcal food poisoning have not been clearly defined. It is difficult, if not impossible, to determine those conditions required to render food poisonous because no satisfactory laboratory test has been found for the presence of staphylococcus enterotoxin in food (5-7). At present, the only means of clarifying these factors appears to be through analysis of unselected outbreaks of this disease.

Ninety-five outbreaks of staphylococcal food poisoning in 1955 and 1956, reported in the weekly communicable disease summaries issued by the Public Health Service, were surveyed. More complete data on 89 of them were obtained from the State, county, and city health officers reporting the incidents.

Analysis of Outbreaks

The diagnosis of staphylococcal food poisoning is generally based on circumstantial evidence, not on demonstrated presence of enterotoxin in food. In this series the diagnosis was based on opinions of health officers originally

Dr. Hodge, who died November 28, 1958, was medical supervisor of the general services department of E. I. du Pont de Nemours & Co., Wilmington, Del., and for several years served on the medical staff of the Johns Hopkins Hospital, Baltimore.

reporting the outbreaks and on the finding of staphylococci in food. Since staphylococci are ubiquitous and many strains are not enterotoxigenic, the mere presence of staphylococci in food is not sound evidence for the diagnosis of this disease. However, in this survey, the diagnosis of staphylococcal food poisoning was supported by two types of supplementary evidence: the type of staphylococcus found in the incriminated food and the incubation periods of the outbreaks.

In the 75 outbreaks which reported such information, the organisms considered to be staphylococci were classified as follows:

Classification	Number of outbreaks
Coagulase positive.....	53
Coagulase negative.....	5
<i>Staphylococcus aureus</i>	45
<i>Staphylococcus albus</i>	1
Hemolytic	28

Thus, of 75 outbreaks, 71 percent of the staphylococci were coagulase positive; 60 percent, *aureus*; and 37 percent were hemolytic. Phage typing and bacterial counts were each reported in three instances, and kitten test for presence of enterotoxin once—too seldom to be of significance. These data indicate, but do not prove, that the organisms generally found were enterotoxigenic.

The incubation periods were recorded in 77 outbreaks.

Incubation period	Number of outbreaks	Percent of outbreaks
1-4 hours.....	61	79.2
5-8 hours.....	11	14.3
More than 8 hours.....	5	6.5

The incubation periods in this series agree with those accepted for this disease. In Feig's series (8), the incubation periods in 50.5 percent of the outbreaks of staphylococcal food

poisoning were less than 4 hours and in 86 per cent were less than 8 hours. Comparison of incubation periods of staphylococcal food poisoning with those of other common foodborne diseases shows the importance of this particular item. Feig reported the median incubation period of salmonellosis as 19.9 hours and of dysentery as 53.4 hours, and Dack (9) reported the incubation period of botulism as 12 hours to many days. Consequently, it appears that the outbreaks surveyed were classified as staphylococcal food poisoning with reasonable accuracy.

Factors Responsible

Dack showed that staphylococcal food poisoning may result after ingestion of certain foods which had been contaminated by enterotoxigenic staphylococci and had remained at proper temperatures long enough to produce dangerous amounts of enterotoxin. Overt infections of food handlers and uncleanliness have been commonly assumed to be the sources of contamination of food, although no general survey has been reported to determine the overall significance of such infections or unclean practices. Furthermore, types of food capable of acting as vehicles of this disease and methods of handling food permitting formation of dangerous amounts of enterotoxin have not been clearly defined.

Types of Food Acting as Vehicles

In 94 out of 95 outbreaks, the vehicle of this disease was reported as cooked food, which contained large proportions of protein. This is in agreement with other observations. In 63 outbreaks, or 67 percent, the vehicles were food mixtures such as tuna salad, turkey salad, creamed chicken, potato salad, meat loaf, chicken pie, egg salad, and cream-filled pastries. Such mixtures are usually handled extensively after cooking.

Raw and freshly cooked meats were not reported in this series and cannot be found recorded in the literature as the vehicle of staphylococcal food poisoning, regardless of state of preservation of meat prior to cooking. The fact that many people throughout the world consume putrid meat with impunity indicates

that raw foods probably are incapable of acting as vehicles of this disease. Unfortunately, no experiments have been reported to substantiate or deny this thesis.

Vegetables, unmixed with high-protein foods, were not reported as the vehicle in any outbreak in this series. Careful differentiation should be made between vegetables mixed with high-protein foods, such as potato salad containing eggs or mashed potatoes prepared with milk and eggs, and vegetables unmixed with any high-protein items.

Food Handlers' Infections and Uncleanliness

Specific questionnaires were sent to all health officers originally reporting outbreaks to determine whether (a) food handlers were examined in connection with the outbreaks, (b) any infection of food handlers was found, (c) the utensils and premises were inspected, and (d) any unclean practices were discovered.

Visible infections of food handlers were reported in only nine outbreaks and were listed as "some lesions on hands of one food handler," "burn from bleach," "infection of eyelid," "blister on hand," "cuts on hand," "two bakers had chronic paronychia," "skin lesions," "healing lesion on hand," and "one cook had eczema." Thus, infections of food handlers, including questionable ones, were not commonly reported in association with outbreaks of staphylococcal food poisoning.

Insanitary practices were reported in only 13 outbreaks. In four outbreaks the practices were described as "unclean" without details given. Other descriptions were "roaches, flies, and unclean premises and equipment," "dirty refrigerator," "debris on slicing machine," "not adequately sanitized," "sanitation poor in pastry shop," "utensils dirty, garbage storage poor," "custard gun eroded," "careless," and "terrible."

Abnormal environmental conditions, including both infections of food handlers and uncleanliness, were reported in a total of 21 outbreaks—1 outbreak reporting both uncleanliness and infection of food handler. In 50 outbreaks, examinations of food handlers and inspections of premises revealed neither infections of food handlers nor uncleanliness. In 24 additional outbreaks, there was no record of

either infection or uncleanness, but reports on this group should be discounted since the data were not complete. Thus, of 71 outbreaks reporting complete information, in 70 percent no obvious environmental conditions which could act as a source of contamination of food by staphylococci were observed.

Methods of Handling Food

The manner of handling vehicles of these outbreaks was investigated through the following questions sent to various health officers. Was the vehicle of food poisoning inadequately refrigerated after cooking, and, if so, under what conditions and how long? Was the vehicle inadequately heated after cooking? If so, under what conditions and how long? Was the food left over or cooked the day before it was consumed?

Leftover food was reported as the vehicle of 81 outbreaks. In only five outbreaks was the vehicle food cooked on the day of consumption. No information was available in nine outbreaks. Thus, leftover food was the reported vehicle of this disease in 94 percent of 86 outbreaks reporting this information.

Unrefrigerated food was reported as the vehicle in 74 of 83 outbreaks supplying information on manner of handling food after cooking. The minimal length of time and temperature of keeping food unrefrigerated are of great importance in defining the rate of enterotoxin production resulting in food poisoning. The length of time food was kept unrefrigerated was tabulated.

<i>Time period</i>	<i>Number of outbreaks</i>
Less than 4 hours.....	6
4-8 hours.....	8
More than 8 hours.....	35
Unknown.....	25

From these data it appears that food can be rendered poisonous within 4 hours. However, careful scrutiny of the six outbreaks in which food was reported unrefrigerated for less than 4 hours shows that two of them involved cream-filled pastries. Here adequate chilling of the custard filling was evidently delayed long after being placed in the refrigerator because of insulation of the pastry capsule. In two other outbreaks food was alternately warmed and in-

adequately chilled. The two remaining instances both involved potato salad, which may have been unchilled for less than 4 hours. The author witnessed one outbreak in which potato salad containing eggs was prepared after 8 a.m. and consumed at 11:30 a.m.; six cases of staphylococcal food poisoning resulted. These cases indicate that unrefrigerated, cooked protein food may become poisonous within 4 hours, but that a period of 8 hours or longer is more common.

No precise information regarding the temperatures which permitted food to become poisonous could be obtained by examination of the circumstances of keeping the vehicles. Temperatures were recorded predominantly as "room temperature."

In 13 outbreaks, cooked protein food was reported inadequately heated. The circumstances appear to have been nearly ideal for bacterial growth: in five instances food was kept on a warm steamtable; and in one instance each in defective oven, in warming oven, under burnt-out infrared lamps, on warming table, and in oven with pilot light burning. The specific circumstances were not mentioned in three instances.

In four outbreaks the food was constantly refrigerated after cooking. Two of these outbreaks involved Boston cream pie and chocolate eclairs, in which encasing pastry acts as efficient insulation. We have found that 3 hours or more are required to lower the temperature of custard within eclairs from 80° to 50° F. when refrigerated constantly at 38° to 42° F. Thus, custard-filled pastries reported constantly refrigerated are, in fact, not chilled for a period of some hours. In the third outbreak the vehicle had been refrigerated in a thick mass in large containers, while the fourth outbreak involved tuna salad prepared with leftover deviled eggs. It seems likely that the vehicle in each of these four outbreaks was not promptly, constantly, and adequately chilled.

Table 1 summarizes the results of this survey. The vehicle in 99 percent of the outbreaks was cooked food which contained large proportions of protein, strong evidence that other types of food such as raw food, vegetables, and other low-protein foods are incapable of acting as vehicles of this disease. Since 70 percent of 71

outbreaks were free from obvious infections of food handlers and without unclean practices, it appears sound to conclude that such abnormal environmental conditions are not the prevailing factors determining the development of this disease. On the other hand, in 83 outbreaks reported on fully, the vehicle was high-protein food, unrefrigerated after cooking in 74 instances, kept warm after cooking in 13 instances, and in 8 instances the food was alternately warmed and left unrefrigerated. Therefore, in 79 out of 83 outbreaks the vehicle was unrefrigerated or warmed after cooking, or both. These numbers clearly show that the determining factor in the development of staphylococcal food poisoning lies in permitting cooked protein food to remain warm or at room temperature for periods of 4 hours or longer.

Discussion

Outbreaks of staphylococcal food poisoning have been generally considered to be dependent on two major factors: (a) some abnormal source of contamination of food by enterotoxigenic staphylococci, such as infections of food handlers; and (b) keeping food under conditions that permit dangerous amounts of enterotoxin to form. In view of the relative infre-

quency of abnormal environmental conditions, it seems clear that food may be commonly contaminated by enterotoxigenic staphylococci under apparently normal, sanitary conditions.

Actually, a large percentage of normal persons have been shown to be carriers of pathogenic staphylococci. Getting and associates (10) reported that 18 percent of 122 food handlers who were apparently free of any infections but who were associated with 10 outbreaks of staphylococcal food poisoning were carriers of strains of staphylococci apparently identical with those strains found in the incriminated food. Allison (5) reported 33 percent of healthy persons as carriers of coagulase positive strains of staphylococci in the gastrointestinal tract. Blair (11) states, "Potentially pathogenic forms [of staphylococci] are constantly carried on the skin or in the nose by approximately 20 and 50 percent, respectively, of all individuals." In view of the large percentage of healthy persons who carry pathogenic staphylococci, it seems logical to assume that virtually all food may become contaminated by these organisms, regardless of the state of cleanliness and the presence or absence of infections in food handlers.

In this series of outbreaks there is sound evidence that staphylococcal food poisoning occurs only when cooked protein food remains for some time at approximately room temperature. None of the outbreaks involved consumption of freshly cooked food. These facts are not new, except in one respect. They indicate that this disease develops when protein food is neglected after cooking rather than because of a multitude of factors. They show that immaculate cleanliness and freedom from infection will not prevent outbreaks of staphylococcal food poisoning.

Prevention

All recommendations for the control of this disease have one objective: to prevent the staphylococci present in cooked protein food from forming enterotoxin. Attempts to keep food uncontaminated with staphylococci by cleanliness and isolation of food handlers appear doomed to failure because of the widespread presence of the organism. Consequently,

Table 1. Summary of responsible factors in 95 outbreaks of staphylococcal food poisoning in the United States, 1955-56

Factors	Outbreaks		Number of outbreaks reporting this type of data
	Number	Percent	
Types of food:			
Cooked high-protein	94	99	95
Leftover	81	94	86
Food mixtures	63	67	95
Fresh cooked meat	0	-----	95
Raw meat	0	-----	95
Vegetables only	0	-----	95
Environment:			
Satisfactory	50	70	71
Uncleanliness	13	18	71
Infections of handlers	9	13	71
Method of handling food after cooking:			
Unrefrigerated or warmed, or both	79	95	83
Unrefrigerated	74	89	83
Warmed	13	16	83

effective points of attack lie in keeping cooked protein food at such temperatures that staphylococci cannot form enterotoxin, and limiting the length of time cooked protein food is kept at dangerous temperatures.

Segalove and Dack (12) reported the length of time and temperature necessary to produce enterotoxin in the laboratory. However, they state that much greater time is required to produce enterotoxin under laboratory conditions than is reportedly required to render food poisonous. Thus, their experiments are not strictly applicable for the control of this disease. In the absence of precise knowledge, these standards of temperatures and limits of time which may safeguard food have been chosen arbitrarily:

1. 40° F. is the maximum temperature for keeping cold, cooked protein food; 50° F. has been recommended but Evans and Niven (13) found that enterotoxigenic staphylococci grow well at this temperature. Segalove and Dack (12) showed that the rate of enterotoxin production was progressively retarded with lowering the temperature below 98.6° F. Since modern refrigerators may be adjusted with ease to temperatures of 40° F. and lower, this level appears advisable.

2. 140° F. is the minimum temperature for keeping hot cooked food since this is the reported thermal death point of staphylococci (11).

3. Three hours is the maximum length of time cooked protein food should be kept between 40° and 140° F., including the time required for chilling. This means the total cumulative time that food remains in this temperature range. The length of each exposure to temperatures 40°-140° F. must be added to that of all previous exposures when leftover food is involved.

While these recommendations are simple in principle, they are difficult in practice. Miller and Smull (14) reported that the quickest chilling of 1-gallon lots of potato salad requires 3 hours after being placed on beds of ice. Lewis and associates (15) recommended chilling food in shallow, flat pans rather than in deep containers; and Black and Lewis (16) recommended refrigerating food while hot.

In the author's experience, the most rapid way of chilling food is to place it in flat, stainless steel pans in a freezing compartment rather than in the refrigerator. For example, it was found that the internal temperature of ½-gallon lots of potato salad was lowered from 65° to 41° F. within 35 minutes after being placed in the freezer at 14° F., while it required 80 minutes to lower the temperature of control lots from 65° to 46° F. after being placed in the refrigerator at 40°-44° F. Utilization of the freezing compartment of refrigerators appears the most effective way yet found to hurdle a major problem in controlling this disease—the delay in chilling cooked food.

In contrast to the difficulty in chilling food, rapid heating is relatively simple because of the large heat differential. In this survey and in the author's experience, inadequate heating of food usually arises from gross negligence—placing food in warm ovens; keeping food on a steamtable for many hours after the heat has been turned off; lowering the temperature of the steamtable because workers find its heat objectionable; mixing hot and cold items without subsequent heating, such as mixing cold chicken with hot cream sauce; warming leftover food rather than heating it thoroughly; and judging temperature of food by temperature of the water bath. In one instance the temperature of the water bath was 160° F., while that of the mass of food was 90° F.

There is often great discrepancy between the temperature of food and temperature of its environment, whether the environment be a water bath or refrigerator. Furthermore, the rate of chilling or heating food cannot be predetermined by sizes or types of containers or by mass of food, since the varied consistencies of food result in varied rates of heat conduction. Consequently, the only means of determining that food is adequately chilled is to insert a thermometer into the mass of food.

Certain problem foods should be handled with special precaution. If custard-filled puffs or eclairs are not to be consumed immediately after preparation, Stritar and associates (17) recommend rebaking them at 375° F. for 30 minutes, which these authors found sterilized the custard within the shell. Potato salad,

chicken salad, egg salad, and similar items should not be used as leftovers since the 3-hour safe-time limit is usually consumed in preparing and serving. Foods containing bread or cracker crumbs, such as croquettes, meat loaf, and poultry dressing, pose a problem because the crumbs create air pockets and act as insulation against heating. Such foods should be prepared only for immediate consumption unless the temperature of the interior of the food has risen to more than 150° F. in cooking.

Sandwiches are common vehicles of staphylococcal food poisoning because they are frequently prepared well in advance of consumption and because chilling the filling of the sandwich, the crucial step, is impeded by the encasing bread acting as insulation. When sandwiches are not to be consumed immediately after preparation, the author suggests chilling them by placing them in layers of two in the freezer. Observations, reported in table 2, show that the filling of sandwiches cannot be adequately chilled when the sandwiches are stacked in three layers, even in freezers, but can be adequately chilled in 2 hours when sandwiches are stacked in two layers in a freezer.

Table 2. Rate of chilling ham filling in sandwiches refrigerated under various conditions

Temperature of refrigerator or freezer (degrees Fahrenheit)	Number of layers of sandwiches	Length of time (hours)	Fall of temperatures of ham filling ¹ (degrees Fahrenheit)
38-40-----	3	2	78 to 61
38-40-----	2	2	78 to 53
38-40-----	1	2	78 to 49
8-----	3	2	76 to 58
8-----	2	2	83 to 34
8-----	2	1	83 to 52

¹ Ham filling in center sandwich if in 3 layers.

Finally, some well-known and commonly ignored precautions should be observed. Don't cook food well in advance of intended consumption. Don't forget leftovers, or assume that they are safe because they are in the refrigerator. Don't assume that the refrigerator supplies adequate chilling without testing the temperature. Refrigerator temperatures frequently are above 60° F. due to overloading,

frequent opening of doors, or failure to adjust the cooling system so that the temperature remains constantly below 40° F. Don't mix hot and cold, cooked protein food without thorough heating afterward. Don't assume that boiling questionable food makes it safe to eat, since boiling does not destroy staphylococcus enterotoxin. Don't depend on odor, taste, or appearance of food to determine whether it is safe to eat since the staphylococcus enterotoxin is odorless, colorless, and tasteless (9). Whether cooked protein food is safe to eat or not can be determined only by the total length of time it has been exposed to temperatures between 40° and 140° F.

Summary and Conclusions

A survey of 95 outbreaks of staphylococcal food poisoning shows that the determining factor in the development of this disease lies solely in keeping cooked protein food warm or at room temperature for 4 hours or longer. Of 83 fully reported outbreaks, the vehicles in 95 percent were cooked protein food which was subsequently kept unrefrigerated or warmed, or both.

Contrary to currently accepted theory, it is clear that outbreaks commonly occur when the food is handled cleanly by personnel who are free of infections. The widespread presence of pathogenic staphylococci among healthy persons insures widespread contamination of food regardless of care in handling.

Therefore, recommendations for control of this disease have one objective: to prevent the staphylococci present in cooked protein food from forming enterotoxin.

In the absence of precise knowledge, the following standards were arbitrarily chosen to protect cooked protein food: 40° F. as the maximum temperature for keeping cold, cooked protein food; 140° F. as the minimum temperature for keeping hot, cooked protein food; 3 hours as the maximum length of time cooked protein food should be kept between 40° and 140° F.

Summer Session in Health Statistics

Statistics in the health sciences will be the subject of the 1960 graduate summer session, June 16 to July 30, 1960, sponsored by the accredited Schools of Public Health of the United States.

The University of Minnesota School of Public Health at Minneapolis is the host. The session will be held under a research training grant from the Division of General Medical Sciences of the National Institutes of Health, Public Health Service.

Courses offered will include: statistical methods in public health; management of health agency records; biostatistics in the health sciences; demographic methods in public health; registration and vital records; advanced biostatistics in the health sciences; statistical methods in epidemiology; sampling techniques in the health sciences; statistical methods in biological assay; and a lecture series.

A limited number of fellowships are available. Information may be obtained by writing to Professor J. E. Bearman, Biostatistics Division, University of Minnesota, Minneapolis 14, Minn.

Prevalence of *Cryptococcus neoformans* in Pigeon Habitats

CHESTER W. EMMONS, Ph.D.

THE frequent occurrence of virulent strains of *Cryptococcus neoformans* in pigeon droppings under roosting sites and in old pigeon nests was first reported in 1955 (1). Prompt confirmation of this observation from Japan (2), Cincinnati, Ohio (3), and New York City (4) showed that this is not an unusual or geographically restricted association. The pigeon is not a host to *C. neoformans* but this pathogenic fungus grows as a saprophyte in pigeon manure and can be isolated from the majority of specimens collected in either rural or urban areas.

I have continued investigations of the prevalence of *C. neoformans* in the environment in order to estimate the frequency of man's possible exposure to the fungus and to evaluate in retrospect the accuracy of diagnoses in certain epidemics or focal outbreaks of pneumonitis which have been accepted as histoplasmosis.

Materials and Methods

Most of the specimens studied have been collected in or near Washington, D.C. The specimens, consisting of dried and weathered pigeon manure from old nests or under roosting sites and relatively fresh droppings and soil from a city park where pigeons are fed by visitors, were scooped up into large glass tubes closed with cotton plugs.

Direct cultures were made by transferring

material from the specimen to agar slants. The slants were incubated at 37° C. in order to inhibit growth of many fungi. Part of each specimen was suspended in salt solution and injected intraperitoneally in mice in order to isolate *Histoplasma capsulatum* if it were present. Mice were killed after 1 month and cultures were made from spleen and liver in the manner previously described (1).

Results

In the series reported here, virulent strains of *C. neoformans* which grew at 37° C. were isolated from 63 of 91 specimens. *H. capsulatum* was not isolated from any of the samples, although the methods used have been shown to be adequate for isolation of *H. capsulatum* from hundreds of other soil specimens. The following table shows the types of buildings or environments from which specimens were taken.

Sources of collections	Total number specimens collected	Number specimens positive
Warehouse, former barn.....	15	14
Old school building, now offices.....	10	7
Grain-milling establishment.....	5	3
Cupola on high school building.....	7	7
Window ledges, Federal and municipal office buildings.....	18	17
Public park.....	7	0
Railroad station.....	4	1
Barns (Virginia and Maryland)....	25	14
Total.....	91	63

The warehouse was formerly a dairy barn with two attached silos. For several years

Dr. Emmons is head of the Medical Mycology Section, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Public Health Service.

prior to this study it had been a government warehouse, and at the time the specimens were taken it had been emptied in preparation for demolition. It stood on the grounds of Junior Village in Washington, D.C., and I am indebted to officials of that institution for permission to collect specimens there.

The former public school building in the District of Columbia, now occupied by offices, is an old brick building with a large attic. The floor of the attic was covered with pigeon dung, nests, broken eggs, and carcasses of pigeons. It apparently fits very closely the description of a similarly infested old school building at Plattsburg, N.Y. (5). During the demolition of that building 23 men became ill with a pneumonitis diagnosed in retrospect and on inadequate evidence as histoplasmosis.

The grain-milling establishment attracted large numbers of pigeons and a few birds nested in some of the open buildings.

The cupola of a high school building and the window ledges of Federal and municipal buildings in Washington, D.C., presented the familiar types of shelters used by urban pigeons for nesting and roosting. I am greatly indebted for assistance in collection of specimens from these buildings to Wallace Coleman and Baker Wingfield, General Services Administration, and Clarence Travis, District of Columbia Health Department.

The one positive specimen from a railroad station was on a concrete floor beneath a ledge where pigeons nested.

Collections from barns were from nests on sills and other protected supports and from floors of haymows, as well as on hay piled deeply above mow floors under roosting stations.

Failure to isolate *C. neoformans* from seven soil specimens in a city park, is not conclusive evidence that the fungus does not grow in such areas. Additional samples will be taken from this and other parks.

Discussion

The close association between man and pigeons in cities and in barns in the country, and the growth of *C. neoformans* in pigeon manure in old nests and under roosting sites

present theoretical and practical problems of considerable public health importance. The strains of *C. neoformans* isolated from these sources exhibit the same patterns of variability with respect to degree of virulence for mice, thickness of capsule, and acid production in various carbohydrates as strains of the fungus isolated from fatal cases of cryptococcal meningitis in man. It seems certain that man must be frequently exposed to this pathogenic fungus by inhalation of windblown cells from saprophytic environmental sources.

Knowing that virulent strains of *C. neoformans* are present in man's environment and assuming that cells of the fungus must be inhaled frequently, one can only speculate on the reasons for the infrequent recognition of pulmonary cryptococcosis in man. The most probable explanation is that primary pulmonary lesions occur as they do in histoplasmosis, that these lesions heal spontaneously because of innate resistance of the individual or because of immunity acquired during the slow evolution of the pulmonary lesion, and that the fungus reaches the central nervous system in only a small percentage of cases. Pulmonary lesions are indeed found in some cases of cryptococcal meningitis, and *C. neoformans* has been demonstrated in healed "coin lesions" in persons without active cryptococcosis (6).

Pulmonary cryptococcosis, limited in extent and duration, may be much more prevalent than is currently recognized. Presumptive evidence of extensive but benign pulmonary infection, without dissemination to the central nervous system, can be deduced from a study of certain epidemics of pneumonitis in which the type of exposure almost certainly precludes the presently accepted diagnosis of histoplasmosis, but makes the presumptive diagnosis of pulmonary cryptococcosis very probable.

One of the most interesting of these epidemics was the one at Plattsburg, N.Y., previously mentioned (5). In 1938, 23 men who tore down a school building became ill. The tower of the building "was filled with dead pigeons of various sizes and with pigeon droppings to a height of about 4 feet. Between the roof of the building and the ceiling of the gymnasium was another deposit of manure and dead pigeons about

2 feet in depth." The diagnosis of ornithosis was apparently ruled out. In retrospect, 15 years later, a diagnosis of histoplasmosis was made. The evidence accepted for the diagnosis in this and similar epidemics was hypersensitivity to histoplasmin, positive serologic tests, development of miliary calcification, and isolation of *H. capsulatum* from soil at the point source of the epidemic (7). Serologic cross reactions between cryptococcosis and histoplasmosis occur so that this evidence is equivocal.

In the case of the Plattsburg epidemic, the isolation of *H. capsulatum* from 1 of 24 soil specimens was reported. The soil sample was taken from the dirt floor of a church two doors from the site of the demolished school house some 15 years after the epidemic. The probability of contaminating a soil sample from the air of a laboratory has been discussed in a previous paper (1). The most convincing retrospective evidence against a diagnosis of histoplasmosis in the Plattsburg epidemic is that *H. capsulatum* has never been isolated from accumulations of pigeon manure in the upper floors of a building, but virulent strains of *C. neoformans* are regularly present in such material. Similar evidence against a diagnosis of histoplasmosis and for a diagnosis of pulmonary cryptococcosis can be presented for epidemics of pneumonitis at Warrenton, N.C. (7), and Mandan, N. Dak. (8).

Summary

Virulent strains of *Cryptococcus neoformans* are generally present in pigeon manure in old pigeon nests and under roosting sites. Recent additional isolations of this pathogenic fungus from varied types of rural and urban environments are reported. The frequent occurrence of *C. neoformans* in man's environment presents a hazard not recognized prior to 1955.

Histoplasma capsulatum has not been iso-

lated from pigeon manure in upper floors of buildings. *C. neoformans*, however, is very frequently present in pigeon manure from haymows in barns and from upper floors of buildings which have sheltered pigeons. In view of these facts, the circumstantial evidence for a diagnosis of a previously unrecognized pulmonary form of cryptococcosis is as strong as the circumstantial evidence for a diagnosis of histoplasmosis in certain past epidemics of pneumonitis in men who were exposed to pigeon manure while demolishing old buildings which had sheltered pigeons. Until such epidemics can be studied systematically at the time they occur, instead of in retrospect, and until cultures and adequate serologic studies are made, the etiology of the type of pneumonitis reported will remain equivocal.

The future of the limited purchase-of-service program that the Philadelphia Department of Public Health launched in 1958 may depend on the development and administration of standards mutually acceptable to the purchaser and the supplier.

Contract Care for Indigent Mothers in Philadelphia

HARRIET F. BERGER, M.A.

IN Philadelphia, an indigent expectant mother may deliver her baby free of charge, by courtesy of the city's maternity contract hospitalization program. Now in its second year, this program has reaped immediate practical and political advantages. Whether this limited purchase-of-service program will be expanded to a long-range program of tax-supported hospital and medical care for the needy is likely to depend upon the development and refinement of relevant standards of medical care and the comparative costs of the contract and a municipal program for the medically indigent one-fifth of the city's population.

Over the years the interests of various professional and lay groups foreshadowed a tax-supported and privately administered method of caring for medically needy citizens. The Community Policy Committee on Health and Hospital Services, the Duane committee, a group of 20 citizens appointed by the mayor from government, hospitals, medical schools, the nursing and medical professions, minority groups, industry, and organized labor, concluded in April 1959 that the care of the medically needy, formerly supported by private

charity in voluntary hospitals and clinics, had become a "proper public responsibility." Underscoring this policy, the Community Chest announced in April 1959 that starting in 1961 the chest would no longer pay some 18 voluntary hospitals their annual grant of \$1,300,000 for "charity" cases, because donations from private sources were insufficient to fulfill this essentially governmental obligation.

Despite this "transfer of financial responsibility," the Duane committee did not foresee a similar transfer of administrative responsibility. It recommended that the city purchase service from voluntary hospitals, simultaneously providing care, bolstering to a modest degree the financial condition of the voluntary hospitals (1), and utilizing the community's hospital resources.

The alternative to a purchase-of-service program was to care for these patients at the Blockley Division of Philadelphia General Hospital with accompanying increases in the hospital's capital and operating budgets. Faced with this alternative and supported by various powerful professional, lay, and religious groups with a stake in continuing traditional community patterns of hospital practice, the city embarked on its contract maternity hospitalization program under the impetus of the closing in January 1958 of the uneconomic Northern Division of the Philadelphia General Hospital.

Designed to care initially for the Northern Division's maternity patients, the new agree-

Mrs. Berger's paper is based on research undertaken while working toward a doctor of philosophy degree in the department of political science of the University of Pennsylvania, Philadelphia. She is a former labor education specialist for the American Labor Education Service.

ments in 1958 provided maternity care at the Temple University Hospital for 1,400 patients at a total cost of \$217,000. In 1959 the department expanded the program to cover 2,000 patients at a total cost of \$300,000 at Hahnemann Hospital as well as Temple. Other indigent maternity patients, about 25 percent of the estimated universe of medically needy maternity patients, are delivered at the Blockley Division and the rest find their way to voluntary hospitals supported by fees, private funds, and State aid, which are not in the contract program.

In 1955 the Philadelphia Board of Health estimated that 21.7 percent, or 462,618 persons, of the total 2,100,000 population could be defined as medically needy. The 1959 expansion of the maternity hospitalization program parallels the recommendation of the Community Policy Committee on Health and Hospital Services that the city council provide "additional financial assistance to voluntary hospitals initially in the field of additional care for maternity cases and for out-patient service" (7). Therefore, the issues of the current program are viewed in the light of a possible expansion in maternity and other hospital and clinic services, perhaps to the extent of a comprehensive tax-supported medical care and hospitalization program for the needy.

The Agreements

The agreements between the city and Temple and Hahnemann Hospitals provide for the payment of \$150 per confinement provided no payment is received from any other sources for complete care of indigent maternity patients. Benefits include a minimum of five prenatal visits to the clinic, treatment of special conditions of pregnancy, delivery including use of operating room, if needed, a minimum of 5 days of hospitalization, care of the infant, and post-natal care.

Eligibility for the program is determined by the same tests applied to persons who seek free care at Philadelphia General Hospital which has worked out a standard of eligibility based on income, family size, resources, age, duration and severity of illness, employment opportunities, and past medical expenses, plus a schedule for part payment applied to all hos-

pital patients (2,3). City interviewers, stationed in the areas where most of the patients live, interview applicants and direct eligibles to the proper clinic for prenatal care. A faculty committee of the University of Pennsylvania found that the Philadelphia General Hospital was the only hospital in the State with a carefully rationalized and professionally administered procedure for determining eligibility (4).

Standards of Care

One critical factor of a purchase-of-service program is its quality or standard. The cooperative establishment of standards requires a far more intimate knowledge of and an index to the problems of a maternal health program than now exists. Under the health code the department permits only fully accredited hospitals to operate maternity and infant services, whether or not they participate in the contract program, and accreditation provides a basic minimum standard below which no hospital maternity or pediatric department is allowed to fall. But above the minimum standard a wide area of discretion exists.

The chief of the maternal and child health section of the department of health, who administers the contract program, is concerned most with the health of the pregnant, nonwhite woman, the majority of the city's patients, and the high fetal death rate in this group. However, the traditional crude system of reporting rates of live births, fetal deaths, maternal deaths, and neonatal deaths does not develop adequately the relationship between death and disability and relevant medical, economic, and sociological factors such as medical and hospital facilities, economic distribution, extent of prenatal care, method of delivery, occupation, race, literacy, education, and incidence of toxemia. Recently, the department adopted a regulation requiring reporting information as a basis for the development of a refined index to the management of deficient infants, the complications of pregnancy, and the complications and conditions of maternity. Using the data obtained in this way the department hopes to be able to secure the cooperation of the hospitals and of the obstetric and pediatric chiefs

in establishing better standards of maternity care and compliance with them.

Even before developing a maternal health profile the maternal and child health section attacked one of the major defects of the program, the extremely low standards of prenatal care. Part of the difficulties stems from faulty administrative scheduling of prenatal visits, part from weak motivation of the patients, and part from a lack of coordination between the prenatal clinic and the hospital. As a result the city has been purchasing a delivery service rather than a maternal health program. By decentralizing the clinic program, putting it directly under the jurisdiction of the chief of obstetrical service in whose hospital the patients are delivered, and by refusing to reimburse for patients who are not registered for prenatal care, the city hopes to facilitate clinic visits, fix responsibility, and instill in both patients and attending physicians and nurses a sense of the urgent need for prenatal care.

The limited experience of earlier purchase-of-service programs indicates that the development and administration of mutually acceptable standards may become the critical factor in the success of the program. For example, the wartime Federal Emergency Maternal and Infant Care Program, which started out on a strict indemnity payment basis, concluded by insisting on rigid standards for reimbursement for dependents' medical care in order to assure its beneficiaries of even minimal standards. In many cases, where possible, EMIC took dependents into service hospitals, rather than subject them to the uncertain conditions of voluntary civilian institutions.

The most thorough study of the administrative and financial aspects of tax-supported hospital care for the medically needy in Pennsylvania (4) gives only "incidental consideration to the qualitative and quantitative adequacy of medical institutional facilities." However, the authors of the study state emphatically that the Commonwealth should get full value for every dollar expended through rigorous licensing and inspection procedures, periodic filing of financial reports, and imposition of regular audits; that its own medical staff attached to the department of public assistance enforce standards of medical care with regard to length of stay,

elective procedures, and long-term care; and that local medical staffs undertake medical audits according to State standards.

Costs of Care

The city is taking measures to control the costs of the contract program as well as the costs of its hospital insurance plan for municipal employees. Moving to insure payment only for services received, the department revised its maternity agreements in 1959 to discourage the practice of cutting short the hospitalization period by both patients and hospital. Formerly providing for lump-sum payment, the agreements now establish a sliding scale of reimbursement based on the number of days the patient is in the hospital: \$50 for the first day, \$25 for the second day, and the balance at the rate of approximately \$22.50 a day until the full \$150 is earned.

As subscriber to hospital insurance with the Associated Hospital Service for some 8,000 municipal employees, the city is further concerned with costs of hospital care reflected in premium rates. Between June 1958 and August 1959, AHS premium rates jumped 71.14 percent because of increased utilization and rising hospital costs. In 1958 the city's vigorous participation in the rate hearings of the State Insurance Commission produced the first public record of the complex relationships of the carrier, the participating hospitals, and the subscribers, embracing varying costs among hospitals, establishment of hospital rates and charges, and reimbursements to hospitals, and laid the groundwork for future regulation.

Meeting increasing hospital costs through hospitalization premiums or through reimbursement without exercising direct control of medical care standards and administration may challenge the city as it has already challenged other purchasers of hospital and medical care. For example, the deputy executive medical officer of the Welfare and Retirement Fund, United Mine Workers Association, concludes after 10 years of attempting to purchase hospital and medical care from voluntary hospitals and private practitioners in the Appalachian Mountain mining areas that "contracting out" has resulted in expensive and inferior medicine. He found that construction and operation of its

own hospitals and group practice clinics in some areas was the fund's only satisfactory method of assuring its member beneficiaries quality medicine (5).

In Philadelphia, the administrator of the American Federation of Labor Medical Plan, a diagnostic clinic serving 64,000 members of 30 affiliates, who is a member of the Duane committee, shares this point of view and finds a parallel in it for the city's program. He supported wholeheartedly the closing of the uneconomic Northern Division and the purchase of maternity care for a limited group of indigent maternity patients. Nevertheless, he is concerned about the consequences, both to standards and costs, if and when the contract program is extended into a general medical care program. Contracting out to voluntary hospitals, he believes, will result in the hospitals and other medical care agencies telling the city what kind of medical care they are willing to provide instead of providing the care the city requires and may well push the cost of the program beyond the financial limits set by the city council. He would prefer to see the city develop its own hospital and group practice program to care for the needy and simultaneously serve as a yardstick for the rest of the community.

Meanwhile the AFL Medical Plan and Center is going forward with its program for the construction and operation of its own hospital because its affiliated unions are dissatisfied with the benefits provided for their members through AHS under their collective bargaining agreements. Evidence leading to a similar conclusion on the comparative cost in 1947 of providing care for veterans in civilian hospitals and constructing and operating more Veterans Administration hospitals was given by Admiral Joel T. Boone, M.D., in testimony at the 1947 hearings of the Senate Subcommittee on Labor and Public Welfare on "National Health Programs" (6).

Nevertheless, government purchase of service to provide medical care for the needy is used widely in many jurisdictions, for example, New York State, New York City, and the Federal Government's share of funds spent by the State for vendor payments to public assistance clients. In the private sector, the UMWA

continues to contract out a sizable proportion of hospital care for its fund beneficiaries where no other alternative is practicable. The experience of these entities is timely and relevant in this critical area of Philadelphia's health programs, the establishment and administration of standards of hospital and medical care.

Conclusion

Philadelphia's modest purchase of hospital care for indigent maternity patients contains within it the ingredients of any future expanded tax-supported hospital and medical care program for its needy citizens, the development and enforcement of standards, and the immediate and ultimate costs of care. Perhaps in this program, as former Health Commissioner James P. Dixon hopes, the department of public health may become a "bridge between conventional institutions of medical care and the community as a whole, can assure the community that standards of medical care in these institutions are being maintained (and that they are) capable of meeting health needs . . ." (7). Whether the department achieves this goal depends not only on its own leadership but also on the talents, imagination, and social responsibility of the medical community.

Wide Focus for Industrial Health

A broadened prospect for industrial health was signaled at the 24th Annual Meeting of the Industrial Hygiene Foundation, October 28-29, 1959, at Mellon Institute, Pittsburgh, Pa.

Complementary addresses by Surgeon General Leroy E. Burney, Public Health Service, and George A. Jacoby, director of personnel relations, General Motors Corporation, emphasized that with respect to health and safety services the industrial employee enjoys far better protection on the job than at home or on the street.

Although General Motors employees have a safety record better than average, Jacoby pointed out, of every 13 accidental injuries they suffered last year, 12 happened off the job. He also described the medical care plan provided for General Motors employees and their families.

Dr. Burney began by emphasizing the dependence of the growing urban population upon industrial technology. For example, he cited the staggering effects of disruption of a city's water or electrical system. He also mentioned the slow pace of biological and social change in contrast with industrial transition, with the result that society fails to achieve full benefits of modern technology. For the same reason, it fails to protect itself against emergent hazards. "When hundreds—literally hundreds—of separate political jurisdictions . . . are involved in a single metropolitan area," he said, "such basic requirements as water supply . . . can be provided only with difficulty and at unnecessarily heavy public expense."

Industry has been much quicker to rise to the demands of technological change than government or civic organizations, he noted. "Industry spends billions to eliminate or effectively control hazardous exposures in the working environment," he observed. "In plants operated by responsible, well-organized industries, the worker has better protection than in his community. I do not know of a single one of our urban communities where environmental controls for the protection of the general population measure up in scope and quality to those maintained by the majority of our larger industrial establishments."

"From the point of view of a physician," he added, "it is difficult not to see an inevitable merging of the problems of industrial health with those of community health."

As targets in this process, he named first an increase in knowledge of environmental factors bearing on individual and public well-being; second, application of available knowledge "to the full" in eliminating or controlling environmental hazards.

He concluded, "I do not count myself among those prophets of doom who periodically predict the end of man as a result of his own achievements. The historical means of maintaining a hypothetical ecologic balance are famine, disease, and war. Yet it would be unthinkable not to combat these conditions. The history of man on earth in a fundamental sense is the history of his efforts to win plenty, health, and peace."

Dr. Henry H. Kessler, director of the Kessler

Institute for Rehabilitation, West Orange, N.J., reminisced informally upon events in rehabilitation since he was inducted into this work by Col. Lewis T. Bryant, who told him, "Don't be an ordinary doctor. I want you to know the workman through and through."

"In 40 years," he said, "the concept of rehabilitation has barely dented the consciousness of the public or the medical profession, although cure means rehabilitation in a relatively simple condition, such as a broken arm. Loss of a limb or a spinal injury, however, needs many hands and the support of the whole community. It is a lucky community that can apply all its resources to rehabilitation."

Such a community, he continued, begins before amputation to prepare a patient for the emotional strain: the shock is akin to grief, which needs specific management. "In the mind of the patient are the questions: will I work again? walk? what will happen? Concrete evidence to answer such questions is needed; moving pictures of rehabilitation or personal demonstrations, if possible, reassure patients, where a pat on the back will not."

He also emphasized the value of professional collaboration. Dr. Kessler does not write a prescription for prosthesis unless the maker and the therapist are standing by to consult and advise. Also, he said, fitting of prosthetic devices is a shared endeavor. In the objective of restoring some degree of independence, apart from the medical treatment, testing and place-

ment services, he said, are also essential. Even though some patients are "socially inoperable," most of them can be placed, he said, if not in former positions, in shelter work, or in tasks that can be done at home. Their potentials as a rule are underestimated, he added. "One patient returned to work successfully at his old trade, as a steel rigger on the upper levels, minus his legs."

Recommending a rehabilitation center available to every community, Dr. Kessler favored a minimum size of 40 beds and 60 outpatients. For such an institution, he estimated a need for a staff of 80 and a budget of \$100,000 annually. He said a center could operate at half that size but should not be reduced more than that unless its services were limited to outpatients. About 25 outpatients, he estimated, might be served with 2 physical therapists, 2 occupational therapists, a speech therapist for hemiplegics, and a nurse to coach patients in the simple tasks of daily living.

Affiliation of such a center with a hospital, rather than with a health department, he believes, is likely to offer the most advantages.

Other speakers at the conference dealt with such broad subjects as stream pollution, atmospheric pollution, community zoning, epidemiological methods, food additives, mental health, and radiation.

All papers offered at the meeting are being published in the Archives of Industrial Medicine and Occupational Health.

Nursing Home Services Section

A Nursing Home Services Section has been established within the Chronic Disease Branch, Division of Special Health Services, Bureau of State Services, Public Health Service.

The newly created section will provide consultative services on matters relating to clinical services, administrative management, and licensing of nursing homes and homes for the aged. The unit will conduct studies and analyze needs relating primarily to services given in such facilities and develop guides for their operation. It will also develop guides relating to State licensure laws and rules and regulations pertaining to nursing homes and homes for the aged.

Dr. Bruce Underwood is chief of the section. Other members of the staff are Kenneth R. Nelson, Jr., consultant in administrative management of medical care facilities; Mrs. Frances S. Wolford, nursing consultant; and Mrs. Charlotte Enterline, secretary.

Milk Sanitation Honor Roll for 1958-59

Fifty-three communities have been added to the Public Health Service milk sanitation "honor roll," and 44 communities on the previous list have been dropped. This revision covers the period from January 1, 1958, to December 31, 1959, and includes a total of 295 cities and 100 counties.

Communities on the honor roll have complied substantially with the various items of sanitation contained in the milk ordinance recommended by the U.S. Public Health Service. The State milk sanitation authorities concerned report this compliance to the Service. The rating of 90 percent or more, which is necessary for inclusion on the list, is computed from the weighted average of the percentages of compliance. Separate lists are compiled for communities in which all market milk sold is pasteurized, and for those in which both raw milk and pasteurized milk are sold.

The recommended milk ordinance, on which the milk sanitation ratings are based, is now in effect through voluntary adoption in 491 counties

This compilation is from the Milk and Food Program, Division of Engineering Services of the Bureau of State Services, Public Health Service. The previous listing, with a summary of rules under which a community is included, was published in Public Health Reports, September 1959, pp. 844-847. The rating method is described in PHS Publication No. 678 (Methods of Making Sanitation Ratings of Milksheds).

and 1,425 municipalities. The ordinance also serves as the basis for the regulations of 36 States. In 16 States it is in effect statewide.

The ratings do not represent a complete measure of safety, but they do indicate how closely a community's milk supply conforms with the standards for grade A milk as stated

in the recommended ordinance. High-grade pasteurized milk is safer than high-grade raw milk because of the added protection of pasteurization. The second list, therefore, shows the percentage of pasteurized milk sold in a community which also permits the sale of raw milk.

Although semiannual publication of the list is intended to encourage communities operating under the recommended ordinance to attain and maintain a high level of enforcement of its provisions, no comparison is intended with communities operating under other milk ordinances. Some communities might be deserving of inclusion, but they cannot be listed because no arrangements have been made for determination of their ratings by the State milk sanitation authority concerned. In other cases, the ratings which were submitted have lapsed because they are more than 2 years old. Still other communities, some of which may have high-grade milk supplies, have indicated no desire for rating or inclusion on this list.

Communities awarded milk sanitation ratings of 90 percent or more, 1958-59

NOTE: In these communities the pasteurized market milk shows a 90 percent or more compliance with the grade A pasteurized milk requirements, and the raw market milk shows a 90 percent or more compliance with the grade A raw milk re-

quirements, of the milk ordinance recommended by the U.S. Public Health Service.

Notice particularly the percentage of the milk pasteurized in the various communities listed. This

percentage is an important factor to consider in estimating the safety of a city's milk supply. All milk should be pasteurized, whether commercially or at home, before it is consumed.

Federal Publications

Little Strokes. Hope through research. *PHS Publication No. 689; 1959; 16 pages; 10 cents, \$7.50 per 100.*

Symptoms of little strokes are described and the importance of early professional diagnosis and treatment is emphasized through personalized examples.

Research in prevention and treatment of stroke is interpreted in terms of the program at the National Institute of Neurological Diseases and Blindness and elsewhere. Discussions of experimental strokes in animals, movement of body fluids, narrowing of human blood vessels, use of anticoagulants, and problems of nomenclature are included.

Medical, paramedical, and social workers will find this booklet helpful for students in their respective fields and for stroke patients and their families.

A Digest of State Air Pollution Laws. *PHS Publication No. 711; 1959; by Samuel M. Rogers and Sidney Edelman; 117 pages; 75 cents.*

Significant provisions of State statutes together with a general statement about each act, the organization provided to administer the act, administrative procedures, and penalty or violation provisions are presented.

This digest is intended for use in the examination and evaluation of existing and proposed legislation and in the formulation of new laws. It will be revised from time to time to keep it current with new legislation.

An Industrial Waste Guide to the Cotton Textile Industry. *PHS Publication No. 677; 1959; 23 pages; 25 cents.*

This guide is intended primarily to assist the operators and managers of cotton textile processing plants to use, reduce, and otherwise suitably dispose of their waste waters. It is also designed to inform personnel of regulatory agencies of the sources

and pollutional characteristics of cotton textile wastes and the status of developments in waste treatment.

The fifth in a series, the guide was prepared by the National Stream Sanitation Committee of the American Association of Textile Chemists and Colorists and published by the Public Health Service as a part of the joint government-industry program to reduce water pollution through control of industrial wastes.

Coronary Artery Disease. *PHS Publication No. 145 (Health Information Series No. 68); revised 1959; leaflet; 5 cents, \$2.75 per 100.* Written for the layman. Discusses processes leading to coronary artery disease, latest methods of treatment, and outlook for coronary patients.

Serology Evaluation and Research Assembly, 1956-57. *PHS Publication No. 650; 1959; 214 pages; \$1.25.*

This official report of an evaluation of serologic tests for syphilis, conducted by the Public Health Service through the cooperation of 15 laboratories, includes a comparative analysis of the performance of 13 *Treponema pallidum*, 7 Reiter treponeme, and 18 nontreponemal antigen techniques in testing 1,298 specimens representing 10 syphilitic and nonsyphilitic categories.

Other sections are devoted to the method of study, results reported, summary of results (by category), sensitivity and specificity of individual tests, and comments and conclusions.

Physicians for a Growing America. Report of the Surgeon General's Consultant Group on Medical Education. *PHS Publication No. 709; 1959; 95 pages; 60 cents.*

Fulfilling the increasing need for physicians is considered in relation to number of applicants to medical schools, quality of students, deterrents to medical education, and sources of student support. A dis-

cussion of medical schools emphasizes financing and expansion.

Broad recommendations are offered for action by the schools themselves, other educational institutions, the medical profession, the public, business and philanthropy, the States, and the Federal Government. The need for development of medical educational opportunities in areas now without adequate facilities is stressed.

Rheumatic Heart Disease. *PHS Publication No. 144 (Health Information Series No. 67); revised 1959; leaflet; 5 cents, \$2.75 per 100.* Re-counts the process by which rheumatic fever damages heart valves. Describes the disease's relation to streptococcal infections, its symptoms, and treatment. Stresses importance of prevention.

Animal Ringworm in Public Health. *PHS Publication No. 727; 1960; 61 pages; 35 cents.*

Clinical and epidemiological aspects of ringworm in animals are discussed with emphasis on the mode of transmission to man and the public health importance of these infections. A review of recent surveys of animal ringworm indicates the extent of the problem and the fungus species involved.

Practical methods for the diagnosis of ringworm in animals, including methods for collection of clinical materials and laboratory procedures, are described in detail.

This section carries announcements of new publications prepared by the Public Health Service and of selected publications prepared with Federal support.

Unless otherwise indicated, publications for which prices are quoted are for sale by the Superintendent of Documents, U.S. Government Printing Office, Washington 25, D.C. Orders should be accompanied by cash, check, or money order and should fully identify the publication. Public Health Service publications which do not carry price quotations, as well as single sample copies of those for which prices are shown, can be obtained without charge from the Public Inquiries Branch, Office of Information, Public Health Service, Washington 25, D.C.

The Public Health Service does not supply publications other than its own.

INFLUENZA-PNEUMONIA MORTALITY IN A GROUP OF ABOUT 95 CITIES IN THE UNITED STATES, 1920-1929

By SELWYN D. COLLINS, *Associate Statistician, United States Public Health Service*

Since the influenza pandemic of 1918-19 there have occurred at various times in the United States, as elsewhere, prominent epidemics of respiratory diseases. It is the purpose of this report to enter into a discussion of the etiological relationship between these several epidemics nor to attempt any definition of the features which serve to identify an influenza epidemic. What is undertaken is to study the course of the recorded mortality from certain respiratory diseases week by week in a large group of cities of the United States; to identify from this record the more distinct periods of notably excessive mortality; to measure the excess, as well as may be; to study its distribution in various sections of the United States in each period; and to study the indicated movement of these epidemics from one part of the country to another.

However objective an approach one may wish to make in the study of the phenomena, the fact that the epidemic manifestations are ordinarily recorded as "influenza" in morbidity statistics and "influenza" and "pneumonia" in mortality statistics carries with it an implication that these manifestations were epidemic influenza. In other words, we have been accustomed to call these respiratory epidemics by a single name—"influenza." It may be that this is a correct interpretation. On the other hand, it may be argued that

FEBRUARY 21, 1930, pp. 361-406

Dr. Selwyn D. Collins' work on excess mortality from influenza and pneumonia forms a benchmark for current investigations of influenza. His study of trends and epidemics, extending finally through 1956, used weekly death rates which exceeded the normal seasonal expectancy for these diseases as an approximation of excess mortality in any given week.

Children with Congenital Heart Disease Served in Regional Centers, 1952-56

ALICE D. CHENOWETH, M.D., and SADIE SAFFIAN, M.A.

REGIONAL centers for evaluation and treatment of congenital heart disease in children were initiated by the Children's Bureau at a time when such care was available in few States. The regional centers were planned to augment services under State crippled children's programs.

Though relatively small in total numbers, one of the most rapidly growing services to crippled children is the congenital heart disease program. The number of children receiving physicians' service in 1957 was almost five times the number in 1950, increasing from 2,207 to 10,168 (fig. 1). In 1958, 12,164 children with congenital malformations of the circulatory system were served. Why has this happened?

In 1939, Congress increased the appropriation for crippled children's programs with the understanding that part of these funds would be used by the States to develop services for children with rheumatic heart disease. Few data on the number of children with congenital heart disease in crippled children's programs are available for the decade 1940 to 1950, but reports which we do have suggest that the number was increasing. As could be expected, among the children referred for suspected rheumatic heart disease were children with congenital heart defects.

In 1939, the same year the appropriation was increased for crippled children, Gross (1) re-

ported the first successful surgical treatment of a patient with patent ductus arteriosus. In 1945, Gross (2) and also Crafoord (3) published reports of the correction by surgery of coarctation of the aorta. At about the same time, Blalock and Taussig (4) reported the results of surgical treatment of pulmonary stenosis and pulmonary atresia; Potts' modification (5) came in 1946. Also in 1945, Gross (6) first reported the surgical treatment of congenital vascular ring (double aortic arch). In 1948, Brock (7) reported the feasibility of a direct surgical attack on congenital pulmonary stenosis.

Thus within a 10-year period, tremendous advances were made in the surgical correction of congenital malformations of the circulatory system, chiefly by surgery on blood vessels. Significantly, an early beginning of intracardiac surgery by Brock (7) foreshadowed the brilliant successes which were to follow. Prior to and concurrent with these advances in surgery, diagnostic skills and techniques were being developed and knowledge of physiology and the dynamics of the circulation was being advanced.

Guided by the principle that these surgical advances should be translated into benefits for children, State agencies for crippled children began to arrange care for those children whose defects were amenable to treatment by the procedures then available. A State having a medical center equipped for adequate diagnosis and surgery was frequently called upon to arrange care by other States without such a facility. This was difficult administratively and at times impossible if the State making the request had

Dr. Chenoweth is chief, Program Services Branch, Division of Health Services, and Miss Saffian is a research analyst, Division of Research, Children's Bureau, Social Security Administration, Department of Health, Education, and Welfare.

legal prohibitions against paying for out-of-State care. Appeals to the Children's Bureau for help came from both States and parents.

Because of the publicity given the announcement of the Blalock-Taussig operation, children from all over the world came to the Johns Hopkins Hospital for cardiac evaluation and treatment. The problem of their care became so acute that the hospital sought the assistance of the Maryland State Department of Health, which in turn approached the Children's Bureau. Therefore, in January 1949, the Children's Bureau approved a special B grant to Maryland for services to out-of-State children with congenital heart disease. This grant, which antedated the establishment of regional congenital heart centers, has continued ever since. In March 1950, the Technical Advisory Committee on Programs for the Care of Children with Rheumatic Fever and Heart Disease to the Children's Bureau recommended that every effort be made to provide diagnostic and treatment services to children with congenital heart disease.

As a consequence of these developments, beginning in July 1951, the Children's Bureau set aside annually \$100,000 of reserve fund B for support of regional congenital heart centers. Medical centers which were outstanding and had a record of successful cardiac surgery were to be designated as regional centers provided: the capacity of the center was such that an additional number of children could be served there; the location of the center was such that it would easily serve adjoining States; and the crippled children's agency in the State was willing and able to administer a regional program. Treatment centers were to be located throughout the country in such a way as to provide full geographic coverage.

Five States are now administering regional congenital heart programs. They are: Maryland, Illinois, Minnesota, Texas, and California.

Administration

Though there are some differences, the pattern of administration of the five regional congenital heart centers is much the same. In effect, the crippled children's agency of the State where the medical center is located acts

Figure 1. Children with congenital heart disease served in the crippled children's program, 1950-57

as the agent, and takes responsibility for arranging the kinds of services needed by children referred by other State agencies, including financial arrangements. It also acts as a liaison between the regional center and the referring State.

In general, the States send their cases to the most adjacent center. However, the skill and reputation of the physicians at a particular center, as well as the preferences of the State agency, the child's private physician, and the parents, also determine the selection.

As in other official crippled children's programs, any child under 21 years of age is eligible for service.

Most cases treated by the regional centers are known to the crippled children's agency of the referring State and complete records are sent to the agency of the State where the center is located. Not only is medical data transmitted, namely, provisional diagnosis, history, physical examination, X-ray and laboratory data, but

identifying, social, and financial data as well. Wherever possible, the referring agency works out in advance a complete plan for the child and for at least one parent who must accompany him. This plan includes transportation of child and parent, and arrangements for board and lodging of the parent while the child is at the center. It indicates what payments, if any, parents, voluntary agencies, health insurance, and the referring State agency are prepared to make toward the cost of treatment. Eligibility for acceptance under the regional program is determined by the referring State, medical need being the primary consideration. Determination of financial need is based on a review of such information as cost of care, family income, size of family, outstanding financial obligations, and availability of health insurance. Because of the high cost of cardiovascular surgery, a relatively larger proportion of families are in need of at least partial assistance in the congenital heart program.

The prime objective of the regional heart program is to correct congenital cardiovascular defects. Therefore, after review of available medical data, those children whose conditions are presumed to be operable are selected by the center's staff. Before proper treatment can be planned for a child, however, his exact malformation and cardiac function must be determined; this may require extensive studies at the center. Even if an operation is not advised, referred children are the responsibility of the regional program as long as they remain at the center. If inoperable when first seen, the child is placed on a proper medical regimen and the center keeps a record of the child and his defect so that he can be recalled if later advances in surgical treatment offer an opportunity to improve his condition. Intercurrent illnesses which develop during the stay of the patient at the center may also be covered by funds for the regional heart program.

In general, transportation of parent and child to the center and board and room for parent and child are the responsibility of the referring State agency; inpatient hospital care, including medical consultations, special nursing care, and blood, is the responsibility of the State agency administering the regional heart program. In some cases diagnostic studies, if done on an out-

patient basis at the center, are paid for by the referring State. Convalescent care, if needed, may or may not be paid from regional program funds.

As a basis for future planning for the care of children with congenital heart disease, the Children's Bureau needed information regarding the use which was being made of regional centers. Therefore, in 1952 an individual record form was adopted. It was designed to show disposition of each application and to present some key facts about each child, such as diagnosis, types of care provided and their costs, and the results of treatment. Regional centers began submitting case summaries in 1952; at the end of 1956, individual records were discontinued and an annual summary report substituted. During this period more than 934 different children received services under the regional congenital heart center program. Omitted from this analysis are a very few cases seen in one center which accepted children for only a short period and from which there is incomplete reporting. Also omitted is an unknown number of cases from another center which failed to send in reports for 1956. Together, these omissions are not a substantial number. This analysis, therefore, covers the cardiac treatment of 934 children under the

¹ Based on total, excluding unreported.

regional congenital heart program during the 5 years 1952 through 1956.

The regional congenital heart plan was conceived as a program to supplement, or in some cases to fill gaps in services, but not to supplant the services of State crippled children's agencies. Also, it was regarded as a temporary plan which would not be needed after adequate treatment facilities became available in all States. That it has been a relatively small part of the total crippled children's program for children with congenital heart disease is borne out by the fact that in 1957 the 686 children who received services in the regional centers represented less than 7 percent of the children with

congenital heart disease who received physicians' services in official State crippled children's programs.

Findings

Table 1 shows the States which referred children to the regional centers for the period 1952-56. States with fewer facilities such as Nevada, New Mexico, Arizona, North Dakota, and South Dakota referred relatively larger numbers of children to the regional centers than States such as California, New York, Illinois, and Massachusetts which had their own treatment facilities.

Fifty-four percent of the children seen under the program were girls. In one center the proportion of girls was almost as high as 59 percent. The children were 89.3 percent white and 10.7 percent nonwhite (table 2). This percentage is lower than the proportion of nonwhite to white children in the total population (13 percent), or in the entire crippled children's program (16 percent) in 1956.

Table 3 shows the ages of the children when they were first brought to the centers. The majority were seen before the age of 5 years. The largest number for any one year of age was seen in their first year of life, the second largest number in their second year of life.

¹ Two children excluded. No determination available on whether or not they received surgery.
² Not computed. Base too small.

Figure 2. Percentage of children served at five centers who received surgery under the regional congenital heart program, 1952-56

In the first 3 years of life, the percentage of children who received surgery increased progressively from about 27 percent under 1 year to approximately 32 percent at 1 year and 42 percent at 2 years. At ages 9 and 10 more than one-half of the children received surgery.

Only about 38 percent of the children in the five regional centers received surgical treatment under the regional heart program during the 5-year period 1952-56 (fig. 2). Some children had surgery before 1952, after 1956, under private auspices, or under a State program, and thus their operations were not counted in this study. During this period, however, a number of children were operated on more than once but were counted as one surgical case, for

example, repair of patent ductus followed later by correction of coarctation of the aorta, and a few children had more than one shunting operation, sometimes each of a different type. In addition, a very few children had noncardiac surgery, which was also excluded from this count.

Comparison of the percentage of cases treated surgically at the different regional centers showed variation from 51 percent to 23 percent.

Some of the more common reasons why surgery was not performed were: inoperable defect at this time; essentially correctable condition, return later after more experience has been gained; await open heart surgery; postpone till child is older; defect slight, present disability does not justify the risk of surgery; death of child before date set for surgery; presence of other severe handicaps more disabling than the heart defect; presence of intercurrent infections, especially respiratory infections and measles.

Sometimes parents refused to permit an operation on their child. Some of their reasons for refusal included: probable benefit would not justify risk; change of residence, request for transfer to another center; and diagnostic studies or intercurrent illness delayed operation so long that parents had to return home because of family duties or because father had to return to his job.

In some cases the surgical schedule was so crowded that an appointment could not be given until a later date. In 1957, operation on a large number of cases ready for surgery had

Findings

Table 1 shows the States which referred children to the regional centers for the period 1952-56. States with fewer facilities such as Nevada, New Mexico, Arizona, North Dakota, and South Dakota referred relatively larger numbers of children to the regional centers than States such as California, New York, Illinois, and Massachusetts which had their own treatment facilities.

Fifty-four percent of the children seen under the program were girls. In one center the proportion of girls was almost as high as 59 percent. The children were 89.3 percent white and 10.7 percent nonwhite (table 2). This percentage is lower than the proportion of nonwhite to white children in the total population (13 percent), or in the entire crippled children's program (16 percent) in 1956.

Table 3 shows the ages of the children when they were first brought to the centers. The majority were seen before the age of 5 years. The largest number for any one year of age was seen in their first year of life, the second largest number in their second year of life.

¹ Two children excluded. No determination available on whether or not they received surgery.

² Not computed. Base too small.

singly and with 1 exception occurred more frequently alone than in combination.

The three most frequent malformations by far were: ventricular septal defect which occurred 181 times, alone in 135 children and associated with another cardiovascular defect in 46 children; patent ductus arteriosus, 177 times, alone in 147 children and in combination with other defects in 30 children; and tetralogy of Fallot, 170 times, alone in 164 children and combined with an additional defect in 6 children. More than half of the children who were seen at the regional centers had one of these three defects.

Following in importance according to frequency were: pulmonary stenosis, atrial septal defect, and coarctation of the aorta, transposition of great vessels, aortic stenosis, truncus arteriosus, and tricuspid atresia.

In 57 cases of congenital heart disease, the exact defect was undetermined. In all of these, further diagnostic studies were indicated; in some, the malformations were so complex that even with extensive studies an exact diagnosis was not possible. In a few cases diagnostic studies were not completed for a variety of reasons, such as child's condition became critical during catheterization, was too serious to permit extensive studies, or was so mild that it was deemed inadvisable to risk further studies.

In 21 children the diagnosis was rheumatic heart disease; 1 of these, a 14½-year-old girl, was operated on for relief of "far-advanced mitral stenosis."

Five cases of heart disease were classified as neither congenital nor rheumatic, for example, one case of tuberculous pericarditis with effusion and one of toxic myocarditis.

In 29 children no heart disease was found, 24 probably had functional murmurs and no other pathology, 2 had mediastinal tumors, 1 an enlarged thymus, 1 a nutritional anemia with hemic murmur, and 1 had pleuropericardial adhesion with distortion of pericardium and cardiac displacement with no evidence of cardiovascular disease.

We think it is fair to say that usually the most difficult cases are sent to the regional centers. One has only to review the protocols of children treated in the regional centers to realize what complex defects some of them had,

how desperately ill some of them were on arrival, and what unpredictable and severe complications a few of them developed. The individual record form asked for "other conditions." Probably this item was under-reported.

Twenty-nine children had associated congenital malformations. Included in this group were two cases of mongolism and one other case of mental retardation with a rectal stricture. Excluded were four other cases of mental retardation from unknown cause. Five of these 29 children had multiple congenital deformities. Four had cleft palate; four had situs inversus of abdominal organs; and three had congenital cataracts. One of the children with congenital cataracts also had a hearing loss; it was stated that the mother had German measles in the first trimester.

Twenty-seven serious infections were reported. Five children had subacute bacterial endocarditis (three of the five were cases of tetralogy of Fallot). Reflecting the improved therapy of this condition, none died at the centers and two were reported in "good" condition. Three children had brain abscesses; three children had tuberculosis, one of these had tuberculous pericarditis. Pneumonia was a complication in four cases.

Nineteen children had neurological complications. The seven cases of mental retardation and the three cases of brain abscess have been previously mentioned. Two cases of cerebral palsy were treated for congenital heart disease. One postoperative case of tetralogy of Fallot developed cerebral thrombosis with residual hemiplegia; a 3-month-old infant with transposition of great vessels had a massive bilateral cerebral hemorrhage. One child with coarctation of the aorta and patent ductus had postoperative paraplegia.

Conclusion

Tribute is due the State crippled children's agencies which administer these regional programs. It was a sizable task to submit the records on which this analysis is based. The administration of this program has not been easy, partly because there were patients who did not apply through their home State crippled children's agency. For example, there were emergency cases or destitute families who

to be postponed because funds for the regional congenital heart program were depleted. In 1958, funds were again inadequate.

For those children receiving surgery, nearly two-thirds were described as being in good condition at the time of discharge from the center (table 4). Mortality in surgically treated cases was 14 percent, in nonsurgical 5 percent. A followup study to learn how many children died following their return home and how many continued to do well would be of great value. Some of the children who died without surgery had extremely complex defects, a few were admitted in extremis, and eight died in heart failure. Of those children who did not receive surgery, more than half were unimproved; in contrast, only 9 percent of the surgically treated cases were unimproved. Though a few cases received open heart surgery in 1956, for the most part the period covered by this analysis preceded the open heart era.

Forty of the patients receiving surgery were under 12 months of age upon admission. Nearly half (18) died. Twelve of the deaths were among the 23 infants under 6 months of age. The condition of the infants receiving surgery under the program at discharge was as follows:

Condition at discharge	Age (months)	
	Under 6	6-12
Good -----	7	7
Fair -----	3	2
Unimproved -----	1	2
Died -----	12	6
Total -----	23	17

There were only two cases of patent ductus among these infants, both of whom did well. The three most frequent diagnoses among them were: tetralogy of Fallot (11), tricuspid atresia (6), and transposition of great vessels (4).

Table 5 shows the days of hospitalization for the children receiving surgery; in some instances they represent two or more periods of inpatient care. Nearly half of the cases were hospitalized between 1 and 2 weeks, a quarter were in the hospital between 2 and 3 weeks, one-eighth between 1 and 3 months, and 3 cases as long as 3 months or more.

Table 6 summarizes the diagnostic data as re-

ported by the regional centers. In many cases detailed medical notes copied from the hospital records give supplementary information about the condition of the child and his treatment during his stay at the center in addition to diagnosis. As one might anticipate, a definitive diagnosis had not been established as yet in every case; in slightly more than one-tenth of the cases the diagnosis was reported as probable or questionable.

Tabulation of the medical data presented some difficulty because of variations in reporting diagnostic information. Also, some children had not only complex cardiovascular defects to which no one diagnostic label could be applied, but also other concurrent conditions as well. It was decided in this presentation to give priority to the cardiovascular anomaly (if present) even though other more serious conditions coexisted.

The first 15 diagnoses listed in table 6 occurred in combination with another defect. Thirteen other children had even more complex defects, namely three or more congenital cardiovascular anomalies occurring simultaneously. These were listed under "miscellaneous congenital heart conditions—complex conditions." In each of these children, there was a different combination of defects. Eight of these children died.

Although the first 15 diagnoses, listed in descending order of frequency, occurred in combination, the first 11 of them also occurred

¹ In general, the arrangement of diagnoses is according to incidence.

² The count in this column is by individual diagnoses whether occurring singly or in dual combinations. Any combination of three or more diagnoses is counted once, due in part to difficulties in determining satisfactorily the exact number of conditions. This slight undercount probably does not affect the total number of diagnoses significantly.

³ No entry is made here because this combination of diagnoses is shown above in reverse order.

⁴ Included are multiple diagnoses of three or more conditions, and certain other cardiovascular conditions infrequently reported.

arrived at the center without an appointment, so-called "door-step cases," or cases known only to the center hospital which was unaware of the inadequacy of family resources before admission of the patient, or those children whose parents appealed directly to the President, their Congressman, or the Children's Bureau.

Perhaps the most serious problem has been the inadequacy of funds to meet the demand for service. It was predicted when the regional congenital heart program was launched that the amount of money available to it would probably be too small to meet the demand for services. It was estimated at that time that the average cost per case for diagnostic, surgical, hospital, and related services would be in the neighborhood of \$1,000 which, if approximately correct, meant the amount appropriated would permit complete treatment service for only 100 children per year in the regional centers. The prediction that funds would be inadequate has been borne out with experience. In fiscal year 1958 the Children's Bureau increased the allotment to regional heart centers to \$248,270; in fiscal year 1959, to \$330,000. Both years the demand for services greatly exceeded the amount of funds available so that before the first half-year was over, centers had to refuse services to children unless the home State could pay the total cost of their care.

None of the crippled children's programs which States administer is static, but the unusually rapid advances in the treatment of congenital heart disease have made administration especially difficult. In spite of expenditure of time and effort in trying to arrive at average cost, no figure which is entirely satisfactory has been found. The problem is not only that costs for comparable services are rising, but with rapid advances in the treatment of defects of different types and increasing complexity, more and more complicated diagnostic and treatment procedures are required. Certain generalizations about costs can be made, however. Cost of hospitalization exceeds all other costs as a major item of expense; costs rise as complexity of defect or of corrective surgery increases.

In reviewing the records, occasional mention of health insurance was noted; it was probably under-reported. In about 13 percent of all cases, there was evidence that the family had some type of insurance which paid part of the bill. About one-fifth of the surgical cases, or a higher proportion than the nonsurgical, had some insurance.

We have ignored the human side of the program in this analysis. The anxiety which con-

DDT Resistance in *A. Quadrimaculatus*

WILLIS MATHIS, B.S., JOHN W. KILPATRICK, M.S., M.P.H., and HARRY F. JOHNSON B.S.

RESISTANCE to dieldrin in *Anopheles quadrimaculatus* Say has been demonstrated in Mississippi (1). Although this species showed a lowered susceptibility to BHC and chlordane, it was susceptible to DDT. Kruse and associates (2) reported possible DDT resistance in *A. quadrimaculatus* in the lakes of the Tennessee Valley Authority area, but subsequent studies (3) indicated this presumed resistance was due to other causes. Hawkins and associates (4) stated that DDT was still the insecticide of choice in the area, after 13 years of larvicidal applications. This paper describes the detection of a DDT-resistant population of *A. quadrimaculatus* which was recovered from a tributary of the Clark Hill Reservoir, Ga.

Clark Hill Reservoir is a multipurpose impoundment built and operated by the Corps of Engineers, U.S. Army, on the Savannah River approximately 22 miles north of Augusta, Ga. At maximum power (pool elevation 330 feet above mean sea level) it covers 70,000 acres with a shoreline of 1,060 miles. Impoundment began in 1951 and full pool was reached in May 1953. Average seasonal operating levels cover a range of about 12 feet.

Operational Procedures

Following general recommendations of the Public Health Service regarding construction and project operation for mosquito control, the Corps of Engineers conducted pre- and post-impoundment anopheline density counts in conjunction with shoreline maintenance and a

larviciding program. Beginning in 1952, larvicide treatments were made by contract aircraft, at a rate of 0.08 to 0.20 pound of DDT per acre, to selected areas where weekly adult counts were high. The average number of *A. quadrimaculatus* per station inspection on the entire reservoir and the pounds of DDT applied during the period 1952 through 1959 are given in table 1. Extreme drought in 1954 and 1955 caused a total drawdown of 33.5 feet and failure to fill by about 10.5 feet in 1955, materially reducing the *A. quadrimaculatus* breeding potential during those years. The highest annual average of *A. quadrimaculatus* per station inspection for a single station has occurred each year since 1953 at a stable, station 41-A, adjacent to the Fishing Creek arm of the reservoir in Georgia. Table 2 gives the annual averages of *A. quadrimaculatus* per inspection for this station and the number of DDT treatments in that area per year.

In 1959, late filling of the reservoir (June 5 instead of May 1) and two floods, which caused rising pool elevations in July and September, resulted in high counts of *A. quadrimaculatus*

Mr. Mathis and Mr. Kilpatrick are with the Technical Development Laboratories, Communicable Disease Center, Public Health Service, Savannah, Ga. Mr. Johnson is with the Engineering Division, U.S. Army Engineer District, Savannah, Ga. The studies at the Technical Development Laboratories were accomplished partially with funds provided under a contractual agreement between the Communicable Disease Center and the International Cooperation Administration.

genital heart disease produces in parents, their gratitude when a heavy financial burden is eased by the regional program, their relief and happiness when the surgeon tells them, "his heart is now normal, and he can gradually assume the activities of a normal child," is another story.

What of the future?

The chief cause of heart disease in childhood is now congenital heart disease (8). Hope for children with this condition improves daily as mortality from intracardiac surgery declines and the results continue to improve, also as new treatments are found to help children with more and ever more complex defects and as surgical treatment becomes possible even in the early months of life, when congenital heart disease is a particularly serious problem. Approximately three-fourths of all deaths due to congenital heart disease occur during the first year of life.

No matter how excellent treatment eventually becomes, our ultimate goal is the prevention of congenital heart disease. Though this goal seems far from fulfillment today, hopefully it may be attained in the not too distant future.

PHS Appointments

David E. Price, M.D., chief of the Bureau of State Services, Public Health Service, for the last 2½ years, has been named deputy director of the Service's National Institutes of Health, a position vacant since the retirement of Dr. Cassius J. Van Slyke in December 1959. This appointment and the following key staff changes become effective July 1, 1960.

Theodore J. Bauer, M.D., deputy chief of the Bureau of State Services since 1956, succeeds Dr. Price as bureau chief; and Kenneth M. Endicott, M.D., who has been associate director of the National Institutes of Health since 1959, will serve as director of the National Cancer Institute, succeeding Dr. John R. Heller, who will be on leave to serve as president of the Memorial Sloan-Kettering Cancer Center in New York City.

Robert L. Zobel, M.D., has been appointed medical officer in charge of the Indian Health Area Office

at Albuquerque, N. Mex. Since 1958, he has directed Indian health services in Idaho, Oregon, Washington, Montana, and Wyoming.

Dr. Price was first assigned to the National Institutes of Health in 1946, taking part in developing the research grants program. Associate director of extramural affairs at the institutes for 2 years, he was named Assistant Surgeon General in 1952, and in May 1957, deputy chief of the Bureau of Medical Services.

Dr. Bauer served as chief of the Venereal Disease Division from 1948 to 1953, when he was named chief of the Communicable Disease Center in Atlanta, Ga. Dr. Endicott was chief of the Cancer Chemotherapy National Service Center of the National Cancer Institute for 3½ years, after serving as scientific director of the Division of Research Grants from 1951 to 1955.

Table 4. Percent mortality of field-collected female *A. quadrimaculatus* exposed to DDT-Risella oil papers for 2 or 4 hours

2-----	4	26	23
4-----	4	130	18
Check-----	4	24	4

only minimum mortality of the strain even with a 4-hour exposure period (table 4).

Additional tests with these field-collected specimens and with the Savannah laboratory strain were made at Savannah on September 24 with DDT- and dieldrin-treated papers. The data are given in tables 5 and 6.

To check the possible effect of season on the susceptibility level of field specimens, *A. quadrimaculatus* females were collected in the vicinity of Savannah, Ga., and exposed for 1 hour to 4 percent DDT-Risella oil-treated papers. The 50 specimens so tested gave a mortality of 96 percent, which is the normal response of a DDT-susceptible strain.

Discussion

The preceding data establish that *A. quadrimaculatus* from the Clark Hill Reservoir area are resistant to DDT, both as larvae and adults. The lack of susceptibility data prior to insecticidal treatments does not permit the conclusion that the resistance was developed by the species through selection. However, the history of insecticidal treatment and the rising *A. quadrimaculatus* densities strongly suggest that this is the case.

This occurrence of DDT resistance in a field population of *A. quadrimaculatus* is of considerable significance in view of the fact that intensive efforts by workers of the Tennessee Valley Authority (4) and at the Technical Development Laboratories (5) to produce DDT-resistant strains by laboratory selection of adults or larvae, or both, have been un-

successful. The presence of DDT-resistant *A. quadrimaculatus* in the Clark Hill Reservoir area and the continued absence of DDT-resistant populations in other impoundments (for example, TVA) again emphasize the fact that the same species occurring in various localities may show distinct differences in its response to an insecticide. These differences could be inherent in the genetic makeup of the species or they could arise from variations in the environment.

From the data on dieldrin in tables 3 and 6, it is apparent that the species also is resistant to dieldrin, but the level is below that shown for DDT. The data on adults (table 6) show a definite plateau response to an increase in the concentration of dieldrin; a specific character-

Check-----	20	0	19	0

in many parts of the reservoir. Despite regular applications of DDT larvicide, the weekly adult *A. quadrimaculatus* count at station 41-A was more than 300 specimens for 9 consecutive weeks beginning June 30. During the season the area was larvicided 18 times at approximately weekly intervals from May 7 to September 18.

In late July 1959, samples of DDT larvicides and solvents were submitted to the Technical Development Laboratories, Technology Branch, Communicable Disease Center, for testing their larvicidal action. These tests showed that the insecticide formulations as used in the control operations were fully effective against susceptible *A. quadrimaculatus* larvae. As a result, suspicion arose that the Clark Hill *A.*

quadrimaculatus might be resistant to DDT, and several hundred live adults were brought to the Technical Development Laboratories for testing.

Resistance Tests

The initial tests were run with larvae and adults obtained from eggs laid by field-collected specimens. The data obtained on third instar larvae, compared with results on larvae of the nonresistant Savannah laboratory strain, are given in table 3.

The number of available adults of the Clark Hill strain limited adult tests to the highest concentration of DDT- or dieldrin-Risella oil papers. One-hour exposures to 4 percent DDT-Risella oil paper and to 1.6 percent dieldrin-Risella oil paper gave only 4 and 38 percent kills, respectively. Adult mortalities for the Savannah laboratory strain at those dosages were 100 and 97 percent, respectively.

On September 21 and 22, adult specimens of *A. quadrimaculatus* were collected and tested in the field. Tests on September 21 at 1- and 2-hour exposures to papers impregnated with 1, 2, and 4 percent DDT in Risella oil indicated maximum mortalities of 34 percent, but the check mortality was unusually high (22 percent). On September 22, further tests showed that the maximum DDT concentration gave

Recent Change in Infant Mortality Trend

IWAO M. MORIYAMA, Ph.D.

FOR MANY YEARS the rapid annual decline in infant mortality was noted with considerable satisfaction by health authorities. Because of this continuing decline, the increases in the infant mortality rate in 1957-58 have been viewed with some concern. No specific factors or disease outbreaks have been identified wholly to account for these rises in infant mortality.

At the request of the Children's Bureau, an examination of available information on infant mortality was made. It would appear from this study that there has been a basic change in the infant mortality trend beginning about 1949 or 1950. The events of the past few years served more to call attention to a problem which apparently had its genesis some years ago.

For years, the infant mortality rate declined at a rapid pace (fig. 1). During the period 1933-49, the infant mortality rate for all races decreased about 4.3 percent each year (slope computed by the method of least squares). However, beginning about 1950, the rate of decrease in infant mortality dropped to 2.0 percent per annum.

The mortality experience of white infants follows the same pattern as for the total infant mortality trend. For the nonwhites, the deceleration in the downward trend is even more marked. In the period 1933-49, the nonwhite infant mortality rate decreased 4.6 percent per annum. Between 1950 and 1956, the rate of decline slowed down to 1.2 percent per year.

In 1957, the infant mortality rate increased as a result of the widespread outbreak of influenza. A further rise was noted in the pro-

visional data for 1958, but this change is not clearly attributable solely to the influenza epidemic, which continued into 1958. The infant mortality rate for each month of 1958 except January and November was higher than the rate for the corresponding month of 1957. Taking into consideration the provisional data for 1958 and 1959, it would appear that the national infant mortality trend has almost completely leveled off, starting in 1953.

Significant changes have taken place over the years in the distribution of live births by age of mother, birth order, birth weight, and so on. It was thought that these changes might account for the change in trend of the infant mortality rate. Because mortality among infants of higher birth order or among those born to older mothers is higher than that for lower parity-age of mother groups, it is

Figure 1. Infant mortality rates, by race, United States, 1933-57

Dr. Moriyama is chief, Mortality Analysis Section, National Office of Vital Statistics, Public Health Service.

istic of resistance in field populations of mosquitoes. This resistance to dieldrin was somewhat unexpected since this insecticide has not been employed for mosquito control in the reservoir and its agricultural use in the general area is limited.

Summary

Tests with field-collected adults and with larvae obtained from eggs of field-collected adults established that *Anopheles quadrimaculatus* from the Clark Hill Reservoir, located near Augusta, Ga., are highly resistant to DDT. DDT has been used routinely on certain areas of the reservoir since 1952.

Radiological Health Training

The Division of Radiological Health reports that presentation of short-term technical courses, part of the training program of the Robert A. Taft Sanitary Engineering Center in Cincinnati, is nearing completion of its most successful year. Over 500 professional personnel from Federal agencies, State and local health departments, colleges and universities, and industry attended the 19 sessions of 12 different courses conducted during fiscal year 1960. Added to these were 47 trainees from 11 foreign countries, plus 300 personnel of the division attending special field presentations. This represented more than double the enrollment of the previous year.

The program for fiscal year 1961 is again being expanded. This is reflected in an increase both in the number and frequency with which courses will be presented. New programs include a 1-week field presentation for scientists and engineers on "Environmental Radiation Surveillance"; a special 1-week course on "Radiological Health for Nurses,"

the first such program in this important area of public health; and a 2-week course, entitled, "Orientation in Radiological Health," specifically directed toward health educators and public information personnel.

In addition, sessions of the course on "Basic Radiological Health" are scheduled for presentation at the Southeastern Radiological Health Facility in Montgomery, Ala., and the Southwestern Radiological Health Facility in Las Vegas, Nev., recently dedicated by the Surgeon General. Sessions of the courses on "Radiological Health for X-ray Technicians" and "X-ray Protection" are scheduled for presentation at another new laboratory being developed by the Division of Radiological Health in Rockville, Md.

During the period July 1, 1960-July 1, 1961, requests for further information or reservations in these courses should be directed to the Chief, Training Program, Robert A. Taft Sanitary Engineering Center, 4676 Columbia Parkway, Cincinnati 26, Ohio.

possible for total mortality to be affected by the change in proportion of births by parity, and so on, even if the force of mortality remained unchanged. Adjustment of rates for the changing distribution of live births by birth order and age of mother indicates that these factors do not account for the change in the infant mortality trend. Neither does the changing number of annual births explain this phenomenon.

Although there is no evidence to suggest this possibility, infant mortality rates could be affected by changes in registration practices. For example, it is known that deaths of some babies dying soon after birth are registered as fetal deaths rather than as infant deaths. In a significant number of cases, the total infant mortality rate and, more particularly, the neonatal mortality rate could be affected by this practice. However, there is no indication from the examination of the perinatal (fetal deaths 20 weeks and over and neonatal deaths) mortality rates that such an artifact is involved. All in all, there is little to suggest that the recent change in the infant mortality trend is not real.

In seeking an explanation for the change in the trend of infant mortality, other data were examined. Figure 2 shows the neonatal (under 1 month of age) and the postneonatal (1 to 11 months of age) mortality rates by race. The neonatal mortality rates for whites and nonwhites declined at about the same rate (3.0 percent per year) between 1935 and 1949. About 1950 the rate of decline of neonatal mortality for nonwhite infants leveled off to about 0.4 percent per year. For white infants, the rate of decline after 1950 dropped to 1.7 percent. The same kind of break in trend also occurs in the postneonatal rates, but at an earlier period. For nonwhites, the annual rate of decline prior to 1946 was about 5 percent. Since 1946, the rate of decrease dropped to 1.5 percent per year. For the white infants in the postneonatal period, the rate of decline was 5.2 percent before 1946 as compared with 4.6 percent after 1945. These rates of change were computed by the method of least squares.

A significant feature of the postneonatal mortality trends is the sharp drop in the rates

between 1945 and 1946. Data by cause of death indicate a substantial decrease in the death rates for influenza and pneumonia and for diarrhea and enteritis in 1946, with the consequent change in level of mortality from these causes after 1946. The decline in mortality from influenza and pneumonia and diarrhea and enteritis in 1946 accounted for about 58 percent of the drop in the total postneonatal mortality rate. Smaller but significant decreases in death rates were recorded for congenital malformations, congenital debility, whooping cough, and dysentery.

Age Subdivisions

Because both neonatal and postneonatal mortality have leveled off, it seemed worthwhile examining the data in greater detail to see if the change is concentrated in any particular age group in infancy. A change in trend (fig. 3) is apparent for each age group except 1 to 6 days. Most of the infants that die in the first week of life are born and die in hospitals. The effect of nursery care should be most evident in this age group. While the mortality trend for infants in the first day of life has flattened out, the rate of decline for infants 1 to 6 days old appears to be unchanged throughout the whole period 1933-57, except for a slight break in 1944 and 1945.

For infants 1 to 4 weeks old, the rate of decrease in mortality rates was fairly steep between 1933 and 1955. It is not possible to tell whether or not there has been a change in trend for this group, but the rates for 1956 and 1957 are successively higher than the rate for 1955. For babies 1 month and 2 months of age, the trends appear to have definitely leveled off. For the older infants, 3 to 11 months old, the rate of decline has slowed down since 1946.

Urban-Rural Trends

Examination of infant mortality trends by population-size groups indicates that the trends for cities of every size are affected, but not to the same extent. Although figure 4 presents data only for the dichotomy urban and rural, the trends for each city-size group show that they have flattened out for residents of cities over 25,000 population. The trends for urban places under 25,000 show very much the con-

RATE PER 1,000 LIVE BIRTHS

figuration seen for the rural trend in figure 4. The rates of decline are not as great as those for the larger cities, but the trends have slowed down in an unmistakable manner.

State Trends by Race

Infant mortality rates for individual States were plotted and trend lines were fitted by eye. The annual rate of change or the slope of the trend line is therefore an approximation. For States with a relatively small proportion of nonwhites in the population, data for total infants only were examined. The results are shown under data for white infants in table 1, since the "total" in these cases relates primarily to the experience for white infants.

The infant mortality trends for individual States generally show the same pattern as those for the country as a whole. For the majority

of the States, there has been a marked slowing up of the rate of decline in the past 7 to 10 years. A typical trend is depicted by the data for Vermont (fig. 5).

There are several other patterns involving some 17 States and the District of Columbia. In one of these, there is an apparent reversal in trend, and the rates are now rising. The infant mortality trend for nonwhites in Maryland in figure 5 typifies this pattern. Table 2 lists the States in which the mortality trend for nonwhite infants is rising.

In another small group of States there has been a significant acceleration in the rate of decline in the infant mortality rate (see data for New Mexico, fig. 5). These areas are shown in table 3.

Another pattern involves some 10 States in which there has been no apparent change in

1 No inflection point.

NOTE: "I" refers to trend for period before point of inflection; "II" to trend after change in trend.

Figure 5. Infant mortality trends for selected States, 1933-57

Point of Change in Trends

Of the States experiencing a change in mortality trends, the point at which the change in trend occurred is concentrated around 1950 for the neonatal rates (21 States), whereas the modal group for the postneonatal rates (10 States) is 5 years earlier, 1945. The following shows the distribution of the inflection points for the States where the rate of decline showed a marked deceleration or an increase:

Inflection point	Number of States	
	Neonatal	Post-neonatal
1954-52	7	2
1951-49	21	11
1948-46	3	11
1945-43	2	10
Total	33	34

Although the neonatal mortality trend apparently started to change in a few States about the same time as the postneonatal mortality rates, most of the changes took place

the rate of decline of the infant mortality trend (see trend for Wyoming, fig. 5). With the exception of Maine, the general trend has been continuously downward in these areas. In Maine, the infant mortality rate took a relatively large drop about 1947 and then continued to decrease at about the same rate as before. The population groups for which no change in the trend could be observed are as follows:

State	Population group
Maine-----	Total
Massachusetts-----	Nonwhite
Kentucky-----	White
Tennessee-----	White
Alabama-----	White
Texas-----	White
Idaho-----	Total
Wyoming-----	Total
Arizona-----	White
Arizona-----	Nonwhite
Nevada-----	Total

With the exception of Massachusetts and Arizona, the above groups generally involve white infants. Most of these States are in the South or in the Mountain division and they represent about one-third of the States in their respective geographic divisions.

Point of Change by Race

Estimates of the point of inflection indicate that the changes in trend did not occur at the same time in all States. For the States which experienced a slowing down of the rate of change or an actual increase in mortality, the point of change came between 1945 and 1953. For the nonwhites, the modal year was 1947, whereas for the whites the mode came several years later in 1950.

The following table shows the points of inflection in the infant mortality rates by States for those racial groups for which there has been a deceleration in the rate of decline, or a reversal in trend.

Point of inflection	White	Nonwhite
1953-----	2	1
1952-----	3	0
1951-----	7	1
1950-----	16	6
1949-----	2	4
1948-----	2	3
1947-----	4	8
1946-----	1	2
1945-----	0	2

The point of inflection in the trend line is significant since it indicates the time when some element was introduced or when the cumulative effects of some factor or factors started to produce a change in the infant mortality trend. For more precise estimates of the inflection point, it will be necessary to fit a mathematical curve to the mortality rates.

For a number of States, there appear to be two inflection points. This occurs where there has been a rapid drop in mortality rates over a period of 2 or 3 years before the resumption of a second trend. In 10 States, the infant mortality rates for whites show an abrupt discontinuity in the trend. In nine States, the rates for nonwhites showed a similar break in trend. In only four States, Delaware, Florida, Mississippi, and Washington, did the trends for both whites and nonwhites have two points of inflection.

State Trends by Age

Data by age more clearly delineate the medical problems involved in the death of infants than do those by race (table 4). The District of Columbia is the only area where there has been a reversal in trend for both the neonatal and postneonatal mortality rates. A similar reversal may also be observed in the postneonatal trend for Connecticut. The rates for infants in the postneonatal period in the District of Columbia and Connecticut appear to be increasing about 3 percent a year after decreasing about 8 percent or more up to 1949 or so.

In only two States, West Virginia and New Mexico, has the neonatal mortality been declining faster in the postwar than in the prewar period. On the other hand, there are 13 States where the rate of decline has not changed, and the rates have been decreasing uniformly over the whole period. These States are: Maine, Indiana, Iowa, Missouri, Delaware, Tennessee, Mississippi, Oklahoma, Texas, Idaho, Wyoming, Arizona, and Nevada.

For infants in the postneonatal period the rates are decreasing faster than before in seven States, namely, Maine, West Virginia, Kentucky, Tennessee, Texas, Colorado, and New Mexico. In three States, Wyoming, Arizona, and Nevada, the postneonatal mortality rate has continued to decline without interruption.

in 1950. On the other hand, the postneonatal mortality trends started to change earlier in a relatively large group of States in 1945 and in each succeeding period through 1951. Whatever factors were operating to change the trend of mortality of infants in the postneonatal period had their effects earlier and involved an increasing number of States in the years between 1945 and 1951. For the neonatal group, the trends were affected in two-thirds of the States in the period 1949 to 1951.

Trend by Cause of Death

The usefulness of available information on causes of death among infants is somewhat limited on a time-trend basis because data by detailed age subdivisions have been tabulated only for a list of 45 selected causes. Another problem is that of comparability of data over a long time period. The major changes in the section on "Diseases of Early Infancy" in the Sixth Revision of the International Classification of Diseases and Causes of Death limit the interpretation of data for a number of conditions.

Despite these limitations, certain findings appear pertinent. One significant feature is the remarkable drop between 1945 and 1946 in the infectious and parasitic disease mortality rate, including influenza and pneumonia and diarrhea and enteritis. In one year, the infant mortality rate for these diseases dropped about 30 percent. By and large, there has been a general and fairly rapid decline in mortality rates for infectious diseases such as tuberculosis, syphilis, whooping cough, and dysentery. The death rates for these diseases are now practically at the vanishing point.

Mortality from diarrhea and enteritis, which is still a relatively frequent cause of death among infants in the postneonatal period, but not in the neonatal ages, shows a different pattern of trends. For the postneonatal white infants, there is a continuous declining trend. For nonwhites in the same age group, there does not appear to be any tendency for a continuation of the downward trend after the large decrease in 1946.

The rate of decline of the mortality trend for influenza and pneumonia has changed signifi-

Figure 6. Infant mortality rates for influenza and pneumonia, by race, United States, 1939-57

cantly (fig. 6). For both white and nonwhite infants in the first month of life, there was a marked flattening out of the trend for influenza and pneumonia starting about 1950. For nonwhite neonates, the influenza and pneumonia mortality rates subsequent to 1950 are at a higher level than they have been during the preceding 5-year period. Among infants in the postneonatal period, the influenza and pneumonia trend for nonwhites leveled off shortly after the precipitous drop in 1946. The trend for whites continued to decline until it leveled off starting about 1951.

A most dramatic reversal of trend may be seen in the death rates for respiratory diseases other than influenza and pneumonia (fig. 7). For infants in the neonatal period, the infant mortality rates for this group of respiratory diseases declined until about 1950 and then rose rapidly. The neonatal rate for whites showed a tenfold increase in about 8 years. The rate for nonwhites did not increase as rapidly as the rate for whites but the curve

NOTE: "I" refers to trend for period before point of inflection; "II" to trend after change in trend.

in 1950. On the other hand, the postneonatal mortality trends started to change earlier in a relatively large group of States in 1945 and in each succeeding period through 1951. Whatever factors were operating to change the trend of mortality of infants in the postneonatal period had their effects earlier and involved an increasing number of States in the years between 1945 and 1951. For the neonatal group, the trends were affected in two-thirds of the States in the period 1949 to 1951.

Trend by Cause of Death

The usefulness of available information on causes of death among infants is somewhat limited on a time-trend basis because data by detailed age subdivisions have been tabulated only for a list of 45 selected causes. Another problem is that of comparability of data over a long time period. The major changes in the section on "Diseases of Early Infancy" in the Sixth Revision of the International Classification of Diseases and Causes of Death limit the interpretation of data for a number of conditions.

Despite these limitations, certain findings appear pertinent. One significant feature is the remarkable drop between 1945 and 1946 in the infectious and parasitic disease mortality rate, including influenza and pneumonia and diarrhea and enteritis. In one year, the infant mortality rate for these diseases dropped about 30 percent. By and large, there has been a general and fairly rapid decline in mortality rates for infectious diseases such as tuberculosis, syphilis, whooping cough, and dysentery. The death rates for these diseases are now practically at the vanishing point.

Mortality from diarrhea and enteritis, which is still a relatively frequent cause of death among infants in the postneonatal period, but not in the neonatal ages, shows a different pattern of trends. For the postneonatal white infants, there is a continuous declining trend. For nonwhites in the same age group, there does not appear to be any tendency for a continuation of the downward trend after the large decrease in 1946.

The rate of decline of the mortality trend for influenza and pneumonia has changed signifi-

Figure 6. Infant mortality rates for influenza and pneumonia, by race, United States, 1939-57.

cantly (fig. 6). For both white and nonwhite infants in the first month of life, there was a marked flattening out of the trend for influenza and pneumonia starting about 1950. For nonwhite neonates, the influenza and pneumonia mortality rates subsequent to 1950 are at a higher level than they have been during the preceding 5-year period. Among infants in the postneonatal period, the influenza and pneumonia trend for nonwhites leveled off shortly after the precipitous drop in 1946. The trend for whites continued to decline until it leveled off starting about 1951.

A most dramatic reversal of trend may be seen in the death rates for respiratory diseases other than influenza and pneumonia (fig. 7). For infants in the neonatal period, the infant mortality rates for this group of respiratory diseases declined until about 1950 and then rose rapidly. The neonatal rate for whites showed a tenfold increase in about 8 years. The rate for nonwhites did not increase as rapidly as the rate for whites but the curve

is definitely U-shaped. The same kind of reversal in trend may be seen in the postneonatal mortality rates for this group of respiratory diseases as in the neonatal rates. The rise in the trend of the postneonatal rates started around 1947, whereas that for the neonatal rates started about 1950.

The main components of the group of respiratory diseases other than pneumonia and influenza, for which mortality rates are undergoing an apparent reversal in trend, appear to be hyaline membrane disease for the neonates, and fibrosis of lung and chronic or unspecified interstitial pneumonia for infants in the postneonatal ages. Hyaline membrane disease not otherwise specified is classified under the category "Other diseases of lung and pleura" (International List No. 527.2). Most of the 1,596 deaths classified to "Other diseases of lung and pleura" in 1957 are probably those reported as hyaline membrane

disease. This disease is being reported with increasing frequency. Prior to the recognition of the condition, it was probably reported as immaturity, unqualified, or asphyxia.

Although deaths attributed to hyaline membrane disease probably represent most of the neonatal deaths from respiratory diseases other than pneumonia and influenza, the category "Other chronic interstitial pneumonia" accounts for only a relatively small proportion of postneonatal respiratory disease mortality. In 1957, 709 deaths among infants over 1 month old were assigned to "Other chronic interstitial pneumonia," out of a total of 2,221 deaths for this age group classified as diseases of the respiratory system other than influenza and pneumonia. In some 1,253 postneonatal deaths from this group of respiratory diseases, the precise nature of the diseases involved cannot be identified without further tabulation. Of the possible causes, bronchiectasis may be the

Figure 7. Infant mortality rates for certain respiratory diseases other than influenza and pneumonia, by race, United States, 1939-57

condition which accounts for a large part of the deaths from diseases of the respiratory system other than pneumonia and influenza in the postneonatal period.

The infant mortality rate for congenital malformations is declining for white infants, while for nonwhite infants it is increasing (fig. 8). In both cases, the rate of change in the trend is relatively small.

For the group of diseases classified as diseases of early infancy but excluding pneumonia and diarrhea of the newborn, there has been a relatively steady decline in mortality trend (fig. 8). The rate of decrease is greater for white infants than for nonwhites. However, there is no break in these trends which serves to explain the change in the overall infant mortality trends.

The ill-defined and unknown causes of death among infants represent a relatively large frequency. However, the mortality trend for causes of death so attributed has been declining fairly regularly for all except the postneonatal rates for nonwhite infants. The rate for this group has leveled off somewhat since 1947.

Accidents constitute a relatively frequent cause of death among infants. However, there is nothing unusual in the trend of mortality from violence which can account for the changes in the overall trend. On the other hand, the trend for the residual group, "All other causes," levels out after a period of decline. It was not possible from the data at hand to examine separately the diseases and conditions involved in this residual group.

In summary, it seems clear that influenza and pneumonia are primarily responsible for the change in the infant mortality trend. Although the infant mortality rate for diseases of the respiratory system other than influenza and pneumonia is now less than one-third of the rate for influenza and pneumonia, it is increasing rapidly. Unless it is checked, it will, before too long, exceed the mortality from influenza and pneumonia among infants.

The impact of any change in trend of mortality from any disease on the total mortality trend depends on the relative frequency of the disease. As may be seen in table 5, approximately three-fourths of all neonatal deaths are attributable to the diseases of early

Figure 8. Infant mortality rates, by race, United States, 1939-57

infancy, which are comprised principally of birth injuries, postnatal asphyxia, and prematurity. Next in the order of frequency are the congenital malformations. The infectious diseases rank third, but their relative frequency amounts to only about 9 percent of all deaths in the neonatal period. The pneumonias and other infections of the newborn and hyaline membrane disease are the most significant problems that can be categorized under the infectious diseases. In this connection, there is the problem of classifying hyaline membrane disease because deaths involving this disease may be attributed to atelectasis, pneumonia of newborn, or other diseases of lung and pleura, depending upon the physician's statement of causes of death.

For infants in the postneonatal period, deaths from the infectious diseases predominate. Influenza and pneumonia, and diarrhea and enteritis appear to be the principal problems. There also appear to be certain diseases of the respiratory system, possibly bronchioc-

is definitely U-shaped. The same kind of reversal in trend may be seen in the postneonatal mortality rates for this group of respiratory diseases as in the neonatal rates. The rise in the trend of the postneonatal rates started around 1947, whereas that for the neonatal rates started about 1950.

The main components of the group of respiratory diseases other than pneumonia and influenza, for which mortality rates are undergoing an apparent reversal in trend, appear to be hyaline membrane disease for the neonates, and fibrosis of lung and chronic or unspecified interstitial pneumonia for infants in the postneonatal ages. Hyaline membrane disease not otherwise specified is classified under the category "Other diseases of lung and pleura" (International List No. 527.2). Most of the 1,596 deaths classified to "Other diseases of lung and pleura" in 1957 are probably those reported as hyaline membrane

disease. This disease is being reported with increasing frequency. Prior to the recognition of the condition, it was probably reported as immaturity, unqualified, or asphyxia.

Although deaths attributed to hyaline membrane disease probably represent most of the neonatal deaths from respiratory diseases other than pneumonia and influenza, the category "Other chronic interstitial pneumonia" accounts for only a relatively small proportion of postneonatal respiratory disease mortality. In 1957, 709 deaths among infants over 1 month old were assigned to "Other chronic interstitial pneumonia," out of a total of 2,221 deaths for this age group classified as diseases of the respiratory system other than influenza and pneumonia. In some 1,253 postneonatal deaths from this group of respiratory diseases, the precise nature of the diseases involved cannot be identified without further tabulation. Of the possible causes, bronchiectasis may be the

Figure 7. Infant mortality rates for certain respiratory diseases other than influenza and pneumonia, by race, United States, 1939-57

Figure 9. Infant mortality rates for certain countries of low mortality, 1941-57

However, the postneonatal mortality trend has also been influenced. The infant mortality trends for urban places of 25,000 or more have almost completely flattened out. For smaller cities and rural areas, the rates are still declining, but the rates of decrease have slowed down markedly.

The change in mortality trend has not been limited to any particular section of the country, although the continuing downward trend for many Mountain States has been remarkably unaffected. In a few States, there has been an acceleration in the decline. The degree of leveling off of the trend is not uniform in various parts of the country. In a few areas, the trend of infant mortality appears to be rising.

The problem of the development of drug-resistant strains of organisms has been mentioned frequently. If this were the total explanation for the change in trend of infant mortality, the resistant organisms must have become a problem for the nonwhites almost immediately after the introduction of penicillin whereas, for the white infants, it took several years before the effects became evident. Unfortunately, there is relatively little statistical information on this subject for the country

as a whole. Dauer (1) has reported a steady and rapid increase in deaths from staphylococcal septicemia and pyemia in the total population since 1949, as well as in the deaths from sepsis of the newborn. However, the total number of deaths attributable to such infections is still relatively small. Unless these deaths are indicative of the much greater problem of staphylococcal infections, they do not serve to explain the change in the infant mortality trend.

The change in infant mortality trend appears to be due to the combination of two factors, the change in the rate of decline of mortality from influenza and pneumonia and the slow-changing character of the trend for the perinatal causes of mortality; that is, congenital malformations and certain diseases of early infancy. This may be depicted schematically (fig. 10).

For purposes of simplification, it may be assumed that mortality among infants is due to two major factors, infectious diseases and perinatal causes. Furthermore, it may be assumed that there is no change in the trend for the perinatal causes. Suppose that, at point A, bactericidal agents such as the sulfa drugs were introduced for therapeutic purposes. If

tasis and pulmonary congestion and hypostasis which seem worth while looking into. The diseases of early infancy are no longer of importance in the postneonatal ages, but congenital malformations become relatively of greater significance. Also, deaths from accidents begin to assume greater importance to infants in this age group.

Experience in Other Countries

Data for a number of countries of low infant mortality were examined. These were Norway, Sweden, Denmark, the Netherlands (not shown in chart), England and Wales, New Zealand, and Australia. The infant mortality trends for all of these countries, except New Zealand (not shown in chart), show the same kind of configuration as that observed for the United States (fig. 9). The infant mortality rates for New Zealand have been rather erratic, but the leveling-off effect is there from 1954. In the other countries, the turning point in the trend appears to be between 1949 and 1954.

The trend for Japan, a country with a relatively high infant mortality, suggests that the magnitude of mortality is not a factor in deter-

mining whether or not a leveling-off effect occurs. The infant mortality rates for the various States in the United States also demonstrate this point.

Discussion

The situation with respect to infant mortality trends may be summarized as follows: For years, the infant mortality rates in the United States declined rapidly, principally because of the reduction in mortality from the infectious diseases. Between 1945 and 1946, there was an unusually sharp break in the death rate for the infectious diseases coincident with the availability of penicillin for civilian use. Also a possible factor was the availability of DDT, which had its impact on mortality from the diarrheal diseases. This was followed by a basic change in the overall infant mortality trend. The trends for both whites and nonwhites, and more particularly the latter, have been affected. The sharp leveling off of the trend for nonwhite infants started about 1946; that for white infants, about 1950. The neonatal mortality trend has changed to a greater extent than that for the postneonatal rates.

flat, the combined effect of these trends exerts considerable influence on the trend for all neonatal deaths. Therefore, the neonatal mortality trend has practically leveled off.

For infants in the postneonatal period, the infectious disease mortality still amounts to slightly less than half of all postneonatal deaths among white infants, and over 60 percent for nonwhites. For this group of infants, there is not the same solid floor provided by the congenital malformations and diseases of early infancy as in the case of the neonates.

Therefore, the leveling-off effect of the infectious disease trend is not reinforced as much by the relatively flat trends of mortality from congenital malformations and diseases of early infancy.

The overall infant mortality trend is affected more by the pattern of neonatal mortality trend than by postneonatal death rates. For every three postneonatal deaths, there are now eight neonatal deaths.

From the examination of these data, it would appear that no marked change downward in the infant mortality rate can be expected until the attack on influenza and pneumonia is altered. There is need for detailed epidemiological studies of the circumstances sur-

rounding infant deaths from these infectious diseases to determine the possible causes of their failure to respond to therapy as might be expected. The factors surrounding deaths presently attributed to hyaline membrane disease and other respiratory diseases appear worthwhile exploring.

No substantial progress in reducing infant mortality will be made until there is a breakthrough in dealing with congenital malformations and the diseases of early infancy, such as birth injuries, postnatal asphyxia, and premature delivery of infants. The hard core of the problem has been relatively untouched.

Although a relatively low infant mortality rate has been achieved, the number of infant deaths occurring annually in the United States is exceedingly high, due to the unprecedented number of births since World War II. The total number of infant deaths in the United States in 1958 was 113,789, the largest number ever recorded in the history of the country. The infant mortality problem of today does not appear to be one which can be viewed with complacency.

Community Survey of Polio Vaccinated Urged

Supplies of unused polio vaccine total 26.4 million doses, although more than 90 million Americans still need to be vaccinated, according to Dr. Leroy E. Burney, Surgeon General of the Public Health Service.

For the past 4 years, he pointed out, there has been a surplus of vaccine in the spring and winter followed by a shortage in the summer when the rise of poliomyelitis cases reminds people they should get vaccinated. The problem can be solved only if the following facts are stressed:

- The vaccine is most effective if used before poliomyelitis is prevalent.
- The vaccine manufacturing process takes about 4 months; if demand for vaccine is low in the spring, supplies are likely to be low in the summer, since the spring supply may be outdated by then.
- It is the third shot, due 7 months or more

after the first two that gives the greatest protection. A fourth shot a year after the third adds even greater protection.

Most poliomyelitis epidemics start in neighborhoods with concentrations of unvaccinated people. Infants and children under 5 years of age have accounted for almost half of all paralytic cases in the past 2 years, Dr. Burney said, yet about half of the children in these age groups still lack optimum protection against the disease.

He urged leaders of local medical societies, health departments, and National Foundation chapters to carry out surveys in their communities to find the unvaccinated and persuade them to be vaccinated promptly. Surveys can be completed within a few days through use of a system developed by the Public Health Service, which will be provided to interested communities.

these drugs were 100 percent effective in the treatment of pneumonia, for example, and if all infants with pneumonia were treated with these drugs, the infant mortality rate would drop from A to B in 1 year. In subsequent years, the trend would continue in a straight line BC. However, the drugs do not completely prevent deaths. Furthermore, not all the infant population with pneumonia comes under drug therapy. Therefore, the actual movement of mortality would follow the curve AD. At point D, a new therapeutic agent is introduced, say, penicillin. Assume that this agent is effective in preventing mortality from pneumonia and all other infectious diseases. If the drug were 100 percent effective and all infectious diseases were treated, the mortality rate should drop from D to F and a new trend, FG, would be established. However, not all the infants contracting infectious diseases are treated nor is the antibiotic 100 percent effective. On the other hand, the sharp drop in mortality from D to E is indicative of the effectiveness of penicillin in reducing mortality. A new trend, EG, is established until infectious disease mortality reaches zero at point G. With the elimination of infectious diseases as

causes of death, the infant mortality trend follows the course of mortality from the perinatal causes, G to H, which is essentially flat.

In the recorded data for total infant mortality, the declining trend prior to 1945 may be observed. There is a drop in mortality between 1945 and 1946 followed by a continuation in the downward trend but at a smaller rate of decline. For all infants, this suggests that infectious disease mortality is approaching an asymptote. The rising trend of mortality from respiratory diseases other than influenza and pneumonia is a relatively small but contributing factor in slowing up the rate of decline in infectious disease mortality. The notion of any asymptote for infectious disease mortality as shown in the schematic diagram might be applicable here, but the evidence does not completely support this point of view. The infectious disease mortality rates for non-white infants started to level off at a much higher point than for the whites. Also, these rates declined at a much slower rate for non-whites than for whites immediately after the large decrease in 1946. For white infants, the relative reduction in infectious disease mortality rate in 1946 was much greater than for nonwhites. However, the trend for white infants continued downward without interruption until 1951 when the rates started to decline more slowly but not as slowly as those for non-white infants. The difference in pattern between the trends for whites and nonwhites suggests possible differences in the method of treatment of infectious diseases or the extent of use of available therapeutic agents or procedures. On the other hand, the consistency of the pattern of infant mortality trends internationally indicates a more basic problem which is not peculiar to the United States.

Because the proportion of infectious disease mortality to total deaths is so different in the neonatal as compared with the postneonatal period, the pattern of trends is different. For infants in the neonatal period, deaths from infectious diseases constitute less than 10 percent of mortality from all causes in this group, and most of the deaths (74 percent) are due to the diseases of early infancy. Because the mortality trends of diseases of early infancy and congenital malformations are relatively

Figure 10. Schematic diagram of course of infant mortality, assuming certain changes in mortality from infectious diseases and perinatal cause mortality

Infant Mortality in Pennsylvania, 1954-58

JOHN H. VINYARD, Jr., M.P.H.

ONE of the most striking changes in health statistics in Pennsylvania and the United States can be seen in the infant mortality figures recorded during the last half century. An examination of these data indicates that the infant death rate in Pennsylvania has been reduced from 145.8 per 1,000 live births during the period 1906-09 to less than 25 infant deaths per 1,000 live births during the period 1954-58. A comparable reduction is observable in national statistics; 95.7 during 1915-19 to less than 27 during 1954-58.

Table 1 indicates infant death rates for Pennsylvania, 1906-58, and the expanding birth registration area of the United States, 1915-58. Sharp decreases from period to period occurred in Pennsylvania from 1906 to the late forties and early fifties, but the rate has essentially stabilized since 1953. The period of rapid decline for the United States ended in the mid-forties although the trend remained downward until 1953. The United States rate for each year since 1953 shows very little variation.

Stabilization of the infant death rate at this level is of great concern to the medical profession, since further reduction in mortality during the first year of life is possible. However, from a statistical point of view, if stabilization of the infant death rate has occurred, it is meaningful and is of interest to determine whether an annual change in the rate (either upward or downward) is statistically significant or whether the change is within the inherent variability of a stable rate. Identification of the components of the change in rate is

equally important for planning purposes, regardless of the presence or absence of statistical significance.

White and Nonwhite Mortality

Levels of infant mortality are significantly affected by sex, race, and age at death. These differentials are apparent in table 2. Approximately 42 percent of the total infant mortality occurs within 1 day of birth, 68 percent in less than a week, and 77 percent before 4 weeks of life are completed. Male mortality is about one-third greater than female mortality for both races and at each age level, and nonwhite mortality is about twice as great as white mortality for each sex and at each age level. Even though the mortality differentials by sex and age are large, these factors do not ordinarily contribute significantly to changes in the total rate because their proportional effect on total mortality remains essentially stable.

The greatest differential in mortality is between the white and nonwhite components, and this differential can influence the total mortality rate without any change in the race-specific rates. For example, in 1957 the crude infant death rate was 24.5, the white rate was 22.3, and the nonwhite rate was 44.7; the rates being based on 254,997 live births, of which 229,793 were white and 25,204 nonwhite. Had the 1957 race-specific rates (22.3 and 44.7) remained constant and been applied to the 1958 birth cohort (white, 224,043 and nonwhite, 25,767), there would have been 4,996 white infant deaths and 1,152 nonwhite infant deaths. The total infant mortality rate would then be $(6,148/249,810) \times 1,000$, or a rate of 24.6 per 1,000 live births. While this is a minimal change in

Mr. Vinyard is chief, statistical methods section, division of statistics and records, Pennsylvania Department of Health, Harrisburg.

Radiation Exposure

These comments were offered by Secretary of Health, Education, and Welfare Arthur S. Fleming in response to questions at his news conference of February 25, 1960.

The February 19, 1960, issue of *Science* contains a report of the Ad Hoc Committee of the National Committee on Radiation Protection and Measurements and a covering note by the chairman, Dr. Lauriston S. Taylor. The Ad Hoc Committee report contains no specific numerical recommendations on maximum permissible limits. It does, however, indicate that such limits should be based on factors above natural background radiation, rather than factors below levels at which demonstrable injury has occurred.

The covering note by Dr. Taylor states that the National Committee on Radiation Protection recommends the interim use of the levels recommended by the International Committee on Radiation Protection until the NCRP has completed its study of the recommendations of its subcommittee I. The number for strontium 90 would be 33 micromicrocuries per liter.

It should be emphasized that the so-called permissible limits are only calculated estimates. They will continue to be subject to change one way or another as more and better scientific data are developed about radioactive elements and their effect on the human body.

There has been for some time considerable discussion related to possible lowering of the recommended levels for some elements, such as strontium 90. Further consideration should continue to be given to the amount of strontium 90 which is distributed and retained in the body. A great deal more research is needed to provide data for a more accurate correlation between the amounts found in foodstuffs and their lodgment in the body.

The levels recommended by the NCRP represent thus far the most informed scientific opinion available to us. Pending recommendations to the President by the Federal Radiation Council and the President's action on these recommendations, the Department of Health, Education, and Welfare will continue, as in the past, to relate levels of strontium 90 in milk, water, and food to the values recommended by the NCRP as permissible for lifetime

exposure. This means that for the time being, the Department will use a factor of 33 micromicrocuries per liter for strontium 90 rather than the earlier factor of 80 micromicrocuries per liter.

The Department of Health, Education, and Welfare has never indicated that exposures below these benchmark levels were absolutely safe. At the same time, we have pointed out that the recommended levels relate to exposure over an entire lifetime and may be exceeded by varying amounts and for varying periods without causing appreciable harm to the individual. Measurements of radiation levels in air, water, milk, and food in various parts of the country are useful primarily as indicators of the scope and nature of health problems which may be developing for specific population groups and as guides for corrective action.

It should be noted that the highest count for radiation in the milk sampling network was 37.3 micromicrocuries per liter at St. Louis in April 1959. The highest annual average was 21.1 micromicrocuries per liter at St. Louis for the year ending October 1959.

ED. NOTE: The report of the Ad Hoc Committee of the National Committee on Radiation Protection and Measurements contains these statements in the conclusions:

"The committee believes that present evidence is not sufficient to establish the dose-response curve for somatic effects at low doses. In the absence of such information, the committee has chosen to make the cautious *assumption* that there is a proportional relation between dose and effect and that the effect is independent of dose rate or dose fractionation.

"On this, or any other nonthreshold assumption, it follows that even the smallest dose is associated with some risk. Under these circumstances, the exposure of the population to any increase in radiation should not occur unless there is reason to expect some compensatory benefits."

The report proceeds then to say:

"We believe that the population permissible somatic dose from manmade radiations, excluding medical and dental sources, should not be larger than that due to natural background radiation, without a careful examination of the reasons for, and the expected benefits to society from a larger dose."

the total rate, it is a result of an increase in the proportion of nonwhite live births from 9.9 to 10.3 percent of total live births and not the result of any change in either the white or nonwhite rate.

Conversely, changes may occur in both the white and nonwhite rate with no discernible change in the total rate. The white infant death rate in 1957 was 22.3, or slightly lower than the

1956 white rate of 22.6, while the nonwhite rate in 1957 was 44.7, an increase over the 1956 rate of 42.1. A 0.3 per 1,000 decrease in the white rate counterbalanced a 2.6 per 1,000 increase in the nonwhite rate; the overall crude infant mortality rate was 24.5 for both 1956 and 1957. Because of the mortality differentials between sex, race, and age, and their individual impact on the total infant death rate, no meaningful ap-

than the nonwhite mortality levels during the previous 4 years. The State nonwhite mortality rate is determined to a large degree by mortality levels in two counties. Approximately 63 percent of the nonwhite births each year are to residents of Philadelphia and approximately 15 percent to Allegheny residents. The remaining 22 percent of nonwhite births occur in such small numbers when allocated to specific county of residence that analysis by individual county is not feasible. Table 5 indicates nonwhite infant, neonatal, and natal day mortality for Philadelphia and Allegheny Counties and the rest of the State for the period 1954-58. When the 1958 rates are compared with the 1954-57 mortality level, only the differences observed for Philadelphia are significant at each age level.

A detailed analysis of rates by county has not been attempted (other than that shown for Philadelphia and Allegheny) because the frequencies in most counties are so small that quite wide variation in annual rates can occur without being statistically significant. The infant death rate for the 45 nonmetropolitan counties was the same in 1957 and 1958 (table 6). Births in these counties are predominantly white and are only 22 percent of the State total. The 1958 rate for the 22 metropolitan counties is greater than the 1957 rate (26.0 and 24.8); however, several of the standard metropolitan areas show decreases in 1958.

When infant mortality by cause of death is

examined, it is found that the only noticeable change during the period occurs in 1958. This is a reduction in the number of deaths attributed to "other diseases of the lung and pleural cavity" and a corresponding increase in the number of deaths classified as "ill-defined diseases of early infancy." This is an artificial change due to a 1958 revision in the rules for coding causes of death under the provisions of

praisal of the 1958 infant death rate in relation to previous years can be made without an examination of the component parts of the rate on a sex, race, and age-specific basis.

In table 3 infant death rates by sex and race for each year 1954-58 and the average rates for the 4-year period 1954-57 and the 5-year period 1954-58 are indicated. A test of the significance of the difference between the 1958 rate and 1954-57 average rate was made for each sex-race class.

In the table, P is the probability that a difference as great as or greater than the observed difference between the 1958 rate and the 1954-57 average rate could occur due to chance alone. If $P = 0.05$ or any smaller value is established as significant, as is conventional, the differences in the white rates of the magnitude observed could occur very frequently due to chance alone, while the nonwhite differences are large enough to be statistically significant. That is, it is very unlikely that 1958 nonwhite mortality is consistent with the 1954-57 nonwhite mortality level.

Comparable data for neonatal death rates (infants under 4 weeks) show similar results (table 3). The 1958 rates for white infants are not significantly different from the 1954-57 average, and the nonwhite rates differ significantly.

In natal day mortality, differences in the white rates again are not significant (table 3). The nonwhite differences are either significant or approach significance. However the probabilities shown indicate that these changes are considerably more likely to be due to inherent

variability than were the 1958 nonwhite rates at other age levels.

Table 4 indicates mortality rates of infants living less than 1 week. The differences tested in this table are between the 1958 rate and the average rate for 1956-57, because data for 1954 and 1955 were not classified to define infants living less than 1 week. The significance of the change in the nonwhite rates is comparable to that found for total nonwhite infant mortality and for nonwhite neonatal mortality. The difference in white rates is not significant, but the probability that differences of this magnitude are due to chance alone is much less than was found for white infant and white neonatal mortality.

These findings indicate that death rates of white infants (at each age level) for 1958 are not significantly higher than the average white mortality observed during the previous 4 years. Mortality of white infants for the 5-year period 1954-58 has been strikingly consistent, and it may be said that the white infant mortality rate has stabilized at a level of approximately 22.7 per 1,000 white live births. (This, of course, does not obviate further reduction of the rate by the application of the full potential of medical and health facilities.)

Area and Cause of Death

The 1958 nonwhite infant death rates (at each age level) were found to be significantly greater

Table 4. Death rates of infants living less than 1 week per 1,000 live births of Pennsylvania residents, by sex and race, 1956-58, and averages 1956-57 and 1956-58

Some Ramifications of Air Contamination

JOHN H. LUDWIG, Sc.D.

THE PUBLIC EFFECT of air pollution, from the standpoint of general community interest and normal governmental regulatory procedures for the country as a whole, is probably the latest area to be added to the list of environmental influences of direct concern to man. No longer do we accept that the world's air resources are unlimited. In a very short period of time we have been brought face to face with a problem which can under proper conditions—or improper—result directly in impairment of health and even death. However, disregarding these spectacular occurrences, the problem is day by day becoming of increasing importance to the community, in that air pollution more and more is making its impact on the everyday living of man by its direct manifestations—eye irritation, visibility reduction, and plant damage, to name a few. More importantly, it poses the broader question of the long-term effects on health and causes one to ponder the future course of the battle between man's quest for a higher standard of living for increasing numbers of people and the garbage they produce. Let us take a brief look at some of the problems we have with us today, with some indication of the work cut out for us in the immediate future.

A statistical study of comparative mortality of 102 causes of death in 163 metropolitan areas in the United States has failed to establish a

disease entity for which air pollution could be cited as the sole cause (1). However, this study did suggest that air pollution in large industrial and population centers contributes in part to the incidence of primary cancer of the trachea, bronchi, lungs, and esophagus. The death rate from emphysema, nonoccupational tuberculosis, and arteriosclerotic heart disease also was considerably higher in metropolitan than in rural areas, but a causal relationship between community air pollution and these diseases has not been established.

Even so, there is still room for speculation along several lines. Repeated exposure to relatively low levels of air pollution may have a causal relation to the development of chronic degenerative diseases; the presence of well-known chemical carcinogens such as benzo-pyrene has been demonstrated in urban community air; extracts of particulate material obtained from a number of cities have produced skin cancer in mice; the irritant nature of air pollution may contribute to the development of cancer by inhibiting the body defense mechanism which normally would remove carcinogen-laden particulate matter from the lungs and respiratory tract; air pollution, as well as smoking, may be a contributing factor to the increasing incidence of lung cancer; in Great Britain there is a specific disease entity, chronic bronchitis, which seems specifically related to air pollution; certain pulmonary or cardio-respiratory diseases may be aggravated by interference with gas diffusion across the respiratory membranes during peak urban air pollution; certain air pollutants may combine with body proteins to form allergenic substances and lead to sensitization and allergic response; and

Dr. Ludwig serves as assistant chief of Air Pollution Engineering Research at the Robert A. Taft Sanitary Engineering Center, Public Health Service. The article represents the essence of a paper delivered before the 47th National Safety Congress and Exposition on October 20, 1959, in Chicago.

the seventh revision of the International Statistical Classification of Diseases, Injuries, and Causes of Deaths. During 1954-57, deaths of infants from "hyaline membrane" were coded to "other diseases of the lung and pleural cavity," while in 1958 these deaths were assigned to "ill-defined diseases of early infancy."

The effect of this revision in coding instructions may be seen in the following table.

Cause	Number of infant deaths				
	1958	1957	1956	1955	1954
Other diseases of the lung and pleural cavity (code 527)-----	13	126	114	105	80
Ill-defined diseases of early infancy (code 773)-----	442	210	225	221	213

Other factors which affect infant mortality such as birth weight, birth order, and age of mother have not been analyzed in detail as have sex, race, and age at death. However it has been observed during this period that there has not been any material change in the proportional distribution of birth weights, birth orders, and ages of mother in the total birth population. The increase in the nonwhite death rate may very well be due to changes in the nonwhite birth population that are not apparent in the total population. Further study of the effect of birth weight, birth order, and age of mother, especially in the nonwhite segment, will be conducted when the 1959 data are available.

All of the rates shown are based on births and deaths occurring in the same year. It is unlikely that computation of these rates on a

cohort basis would affect the findings of this study because the number of white births each year has been fairly constant and the number of nonwhite births has increased only slightly each year. Under these conditions the relative difference in rate from year to year is much the same for each race group using either method of computation.

Summary

An investigation of infant mortality in Pennsylvania at several age levels (under 1 day, under 1 week, under 4 weeks, under 1 year) during 1954-58 indicates that the white mortality rate has essentially stabilized and that the 1958 rate falls within the expected range of inherent variability associated with the average of the 1954-57 mortality level.

The difference between the 1958 nonwhite infant mortality and the 1954-57 average rate at each age level was found to be statistically significant; that is, it is highly unlikely that differences this great could occur due to chance alone. While the nonwhite rates increased throughout the State, only in Philadelphia County were the 1958 rates found to be significantly greater than the 1954-57 averages.

Infant mortality during 1958 in the standard metropolitan areas of the State increased slightly over the 1957 rate, while mortality in the nonmetropolitan counties was the same in both 1957 and 1958.

No real change in mortality from specific causes of death can be identified.

Performance Standards for Health Agencies

Minimum standards of performance for local health departments will be put into effect by the Public Health Council of the New Jersey Department of Health on April 1, 1961. The council had previously prepared a list of recognized activities for health departments, recommended by a committee of local health officers in 1957. The same committee drafted the minimum standards of performance. Its recommendations were adapted with refinements after a public hearing. Copies are available from the New Jersey Department of Health.

A summary of the activities of the New Jersey Department of Health appears in its annual report, dated March 1, 1960.

tributor in direct relation to the increase in the total contribution can we expect to hold our own.

Next, consider the effects of particulate material in the atmosphere, and its effects on the community. In relation to our previous discussion on health, there are convincing laboratory data on animal studies which suggest that the physiological effects of irritant vapors are potentiated in the presence of aerosols. It has been proposed that the effects of air pollution disaster episodes were the result of the synergistic action of two or more atmospheric contaminants, one of which may well have been particulates.

The quantity of dirt contained in the atmosphere is expressed in terms of the sum of suspended material and that which settles out on a plane surface as settleable dust. Measurements made by the Public Health Service's National Air Sampling Network, comprising some 265 stations located throughout the Nation, indicate an alarming difference between the cleanliness of air over our cities, expressed in terms of suspended particulates, as compared with the rural areas. The latter in a broad sense might be considered the "background" level. The National Air Sampling Network collects suspended particulate matter by use of a High-vol sampler, wherein 70,000 cubic feet or so of air are sampled over a 24-hour period. Particulates varying in size from well below a micron to approximately 100 microns are retained on a glass fiber filter.

The results of sampling over the period 1953-57 (fig. 1) indicate a geometric mean particulate concentration over urban areas of 136 micrograms per cubic meter as compared with 33 for nonurban areas, or roughly four times as great (2). Since the distribution of samples is the same—that is, the standard geometric deviations are about equal as shown by the parallelism of the two plots, we can deduct the latter from the former and come up with a plot of "urban minus nonurban," which difference may then be considered as the contribution of urban living to pollution of the air—roughly 100 micrograms per cubic meter. In terms of the air we breathe, amounting to about 200,000 cubic feet of air yearly, the intake of dirt into our lungs attributable to urbanization

comes to about a half a gram per year, not an imposing quantity at first glance, but quite significant in terms of numbers of particles, surface area, penetration into the respiratory system, and chemical content.

Further analysis of these data (3) indicates that dirtiness and population size are related (fig. 2). Even the dirtiest of nonurban sites is much cleaner than the suburban or urban site categories. The 117 cities in the "less than 700,000 population" category are dirtier than their own suburbs, and cleaner than the 11 cities with more than this population. Coastal sites show a markedly different distribution of particulate matter attributable to a constant base of salt from sea sprays.

In terms of settleable dust, sampling over the years from several large cities shows the impact of control measures, but the curves level off indicating the limits imposed by the practicability and economics of further removal (fig. 3). Nonetheless, even for a relatively clean atmosphere with an average of 50 tons of dust per square mile per month, this amounts to about 5 pounds per year on a 9-foot by 12-foot rug, if we care for a comparison in terms of the housewife who is most aware of the annoyances connected with such dustfall.

Concerning the detailed analyses of suspended particulate matter collected by the National Air Sampling Network, a comparison of ratios of the organic fraction to the total particulate collected has been made. The ratio is essentially constant for all categories of stations and equal to about 7 percent of the total particulate. The following tabulation indicates a further breakdown of the organic fraction in terms of the well-known carcinogen, benzo [a] pyrene, for nine American cities in November 1958(4).

City	$\mu\text{g. BaP/gram of particulate}$	$\mu\text{g. BaP/1,000 m.}^3 \text{ of air}$
A-----	5.1	1.9
B-----	30.0	3.2
C-----	32.0	2.0
E-----	29.0	7.0
D-----	54.0	7.6
I-----	70.0	10.3
H-----	98.0	14.4
F-----	102.0	19.6
G-----	106.0	29.9

finally, there may be more than irritation of the eyes, nasal passages, and the respiratory tract associated with "Los Angeles type" smog, even though overall mortality rates in urbanized areas in California do not differ significantly from the rate in rural areas of that State.

This thumbnail report of the effects of air pollution on health is hardly detailed enough to really assess the problem. What it does serve is to point out that the effects of air contaminants are subtle and hidden, evidently seeking out first those whose resistance to stress is minimal—the very old, the chronically ill, and the young, exposed around-the-

clock and over the years. It behooves us to continue our efforts to seek and find the relationship of community air pollution to health, and until that time to take all reasonable measures to control pollutants in all of their forms and to the greatest extent economically feasible. Our desire for a higher standard of living resulting in increased industrialization and larger populations concentrated into urban complexes all adds up to larger quantities of air garbage going into the same atmosphere which is limited in its capacity by relatively unchanging topographical and meteorological conditions; only by reducing the quantity per con-

Figure 1. Cumulative frequency distribution of suspended particulate matter for all stations of the National Air Sampling Network, 1953-57

status, let alone effect additional cleanup beyond present levels.

So far we have given attention only to particulate pollutants in the air. Much less work has been done on general monitoring for gases and vapors on a national scale than for particulates; however, more intensive investigations have been made locally in connection with specific problems. Gaseous pollution problems have invariably been associated with combustion processes: the generation of power, basic metals production, industrial processing, waste disposal, or the operation of family automobiles and house heating. All of us are contributors in direct relation to the type and quantity of fuels we use and the combustion efficiency of the equipment used. In this latter context we refer to total destruction of organic fuels to their basic combustion products—carbon dioxide and water—not merely the recovery of the heating value of the fuel.

Sulfur dioxide has long held the stage as a

universal air pollutant. When one considers that coal, the major source of SO_2 , will continue to be the major source of fuel in the world for some time to come and that vastly larger quantities will be consumed, the picture is not promising, especially in the light of general downgrading in the quality of coal. The trend toward conversion to gas as a fuel source, particularly in the home, and the centralization of coal use for power development in large installations, where combustion is efficient and control is most feasible, promises some improvement. The ultimate solution rests, however, with the development of an economical means for sulfur dioxide removal from flue gases. This is being worked on.

The photochemistry of atmospheric reactions which take place among pollutants after their discharge to the atmosphere opens a whole new field for investigation. Hydrocarbons in general, and in particular the more reactive species, such as olefins, together with nitrogen oxides,

Figure 3. The trend in atmospheric settleable dust loadings for four American cities

Figure 2. Cumulative frequency distribution of suspended particulate matter by population and geographic categories

Plots of the spectra of chromatographic fractions from a large number of air particulate samples indicate that the concentration of benzo[a]pyrene denotes an increase in the concentration of other well-known polynuclear hydrocarbons including the possibility of other polynuclear carcinogens (fig. 4). The peaks at 377, 379, and 382 millimicrons indicate the presence of benzo[a]pyrene, at 401, benzo[k]fluoranthene, at 434, perylene, and at 330, benzo[a]pyrene.

The significance of these data on suspended particulates and settleable dust lies not only in the quantitative amounts and the influence of urbanization and associated industrialization but in the trends which are indicated. Cer-

tainly we expect an increase in urbanization, now estimated to be in direct numbers equal to the Nation's increase in population. This means more and larger cities with a direct increase in the activities necessary to support these populations, both domestic and industrial. Added to this are the waste problems associated with increased per capita production that is inherently coupled with improved standards of living. When these trends are viewed from the standpoint of removal efficiencies for particulate control equipment, the result is even more significant. It is the residual which passes through control devices which must be reduced in direct proportion to the increase in total contribution if we are to even maintain the present

Environmental Radiation Studies

The first two studies of a nationwide series aimed at determining the effects of environmental radiation on the health of large population groups have been initiated by the Public Health Service in cooperation with State and local health authorities. One study will involve residents of San Juan County, N. Mex. The second will focus on the St. Louis, Mo., region, beginning with the St. Louis milkshed.

The locality for the San Juan study is one of the largest uranium producers in the country. Earlier studies have shown that radioactivity from radium in the surface water of the Animas River has been higher than that found in most areas in the United States.

Effective steps have been taken recently to reduce the amounts of radioactive waste discharged into the rivers of this locality. However, extensive data have already been obtained on radioactivity in this environment. Consequently, the area presents an unusually good opportunity for further study to determine the amounts of radioactivity in the elements currently being taken in by people, the amounts of radioactivity they retain, the total "body burden," and the effects upon their health.

In the current project detailed medical and laboratory examinations will be given approximately 100 families totaling about 400 individuals. Teams of Federal and State physicians, nurses, and technicians will obtain complete medical histories of each individual in the cooperating families and determine a typical week's diet. Exact duplicates of typical diets will be analyzed to determine the amount of radioactivity taken in. Body wastes and breath samples will be collected and analyzed to

determine the amount of radioactivity excreted.

Exhaustive study will also be made of the vital statistics of the area. Some aspects of the project will require followup interviews, medical examinations, laboratory studies, and statistical analyses extending for several years. In the near future, this study will be applied to other areas along the Animas and San Juan Rivers.

The St. Louis study seeks to determine the significance of previous findings concerning radiation levels in the area and, in its initial phase, whether previous strontium 90 findings obtain throughout the entire St. Louis milkshed, or only part of it. Though the levels of strontium 90 have been somewhat higher in the St. Louis milkshed than elsewhere, average levels for St. Louis have been below those which the National Committee on Radiation Protection and Measurements considers permissible for lifetime exposure by the general population.

A preliminary survey of dairy farms in the various milksheds serving St. Louis will consist of investigations of water supplies, sources of animal food, climate, farming and animal feeding practices, and other variables that may be associated with different types and levels of radioactivity in milk. The final phase of the milkshed study will consist of field experiments to determine whether, if necessary, the radioactive content of milk can be reduced by modifications in dairy farming practices.

Techniques developed in the St. Louis study will be applied to similar milkshed investigations being planned for several other major metropolitan areas in the United States.

Figure 4. The ultraviolet-visible absorption spectra in pentane of some benzopyrene chromatographic subfraction for five American cities

are at present the major suspects in the fight against "Los Angeles type" smog, with the role of sulfur dioxide and particulates still neither clearly indicted nor exonerated. The intensive endeavors of the past 10 years have increased immensely our store of knowledge of what is happening and how to measure it, but at the same time have broadened the vistas as to possible offending precursor agents and their interactions. The concept of a universal photolyzed reaction product responsible for all effects—eye irritation, plant damage, and visibility reduction, to name the major ones—is giving way to the notion that perhaps different products or

families of products are responsible for the various effects, and that these products may have various modes of formation depending on the vagaries of the precursors, accumulation resulting principally from meteorological conditions, and sunlight conditions.

Next, what are some of the community effects of air pollutants which directly result in economic loss roughly estimated to be around \$2 billion or about \$10 per capita annually? These have been listed many times by many authors, and comprise the gamut from additional cost of soap in the home to depreciation of property values. To name a few we have the extra cost of such household expenses as more frequent laundering, cleaning, redecorating, and replacement of furniture, clothing, and other household or personal materials; similar additional costs in commerce and industry, including more rapid deterioration of products and foodstuffs; increased costs of structural maintenance reflected in cleaning, painting, renovation, and replacement; reduction in life of various types of machinery due to both gaseous and particulate pollutants; increased use of artificial lighting due to reduction in light intensity; the necessity for increased use of air filtration equipment for protection of health or production of special equipment; increased expenses for navigational equipment at municipal airports due to increased visibility restriction by pollutants; additional medical expenses due to both increased irritation of the mucous membranes and accidents attributable to pollution; and finally, as previously mentioned, the added cost of accelerated property deterioration. Indirectly, communities, or the people who live in them, encompassing the major portion of the population, must bear the added expense of services or products required to offset the effects of air pollution. This would include such items as increased costs of agricultural products, both vegetable and animal, due to air pollution.

sive classification, mental health authorities have estimated that some 790,000 beds, approximately one-half the beds in all hospitals in this country, are now occupied by mental patients. Despite this staggering overall total, the States report that, using the present formula of 5 beds per 1,000 population, an additional 421,000 beds for mental patients are required.

State agencies have also emphasized that many of the existing facilities do not permit the use of modern techniques and improved treatment methods in mental care.

Some of the complicating factors which confront planners of mental health facilities were stated by the Surgeon General when he appointed the ad hoc committee.

"In the past," Dr. Burney said, "emphasis was placed on providing large institutions for the care of the mentally ill. Treatment now being offered includes outpatient and emergency service through hospital clinics or mental health centers, increased use of general hospitals for the treatment of psychiatric patients, 'halfway houses,' and nursing homes."

The Surgeon General explained that an adequate program stresses continuity of care and requires a wide spectrum of services, both community based and hospital oriented.

"If social and family ties are not to be weakened, the patient should be treated as near home as possible, even if hospitalization is indicated," Dr. Burney said.

The report, which was read at both conferences, included the following proposed principles for use in developing statewide plans:

- Facilities for the mentally ill, both as to location and type, should be programed and constructed in accordance with a comprehensive statewide plan which provides for a coordinated pattern of service.

- Statewide planning for mental health should represent a joint effort by State and local, public and private agencies concerned with mental health.

- In the interest of providing more effective service to more people, facilities should be designed and utilized to serve multiple needs, when this is consistent with sound treatment practice.

- Construction design should be flexible, to permit future expansion or modification to

other uses, particularly in psychiatric units of general hospitals.

- Treatment should be suited to the patient's need and the patient should be referred to the facility most appropriate to his need. Greater emphasis should be placed on continuity and progressiveness of care.

- Programs for mental health should place increasing emphasis on prevention, early recognition, and early treatment of mental illness.

- Construction of new facilities should be based upon the current concepts of treatment and expected future development.

- Facilities for treatment should be located in terms of easy accessibility to the area of potential need.

- Facilities should be used for the purpose for which programed and staffed, and at the highest levels of efficiency.

- Higher priority should be given to a mental health facility which is a part of or closely affiliated to a general hospital or health center, and to a new facility rather than to a proposal for remodeling an existing facility.

- Increased emphasis should be placed on rehabilitation of the mentally ill and preparation for complete return to home and society at the earliest feasible time.

- Long-term custodial care in mental institutions should be prescribed only as indicated following application of intensive treatment techniques.

- Provision of care and treatment to the senile aged, mentally retarded, and emotionally disturbed should be considered as a part of the State and local mental health program.

The report was read by Dr. Bernard Bucove, director of health, Washington State Department of Health, at the meeting of hospital and medical facilities survey and construction (Hill-Burton) authorities on January 5, and by Dr. Harold L. McPheeters, commissioner of the Kentucky State Department of Mental Health, Louisville, at the mental health authorities' meeting on January 6.

In addition to Bucove and McPheeters, other committee members are:

Dr. John J. Bourne, executive director, New York State Joint Hospital Survey and Planning Commission, Albany; Dr. Dale C. Cam-

Planning Mental Health Facilities

RECENT advances in methods of diagnosis, treatment, and care of the mentally ill present a complexity of problems not only to psychiatrists but to planners of medical facilities as well.

This fact was borne out in a report presented at the Washington conferences of both State Hill-Burton authorities and State mental health authorities called by Surgeon General Leroy E. Burney in January 1960. The report was an account of the activities of an ad hoc committee appointed last August by Dr. Burney. The committee's objective was to plan an attempt to overcome a long-felt need for more adequate facilities for the mentally ill.

Hill-Burton State authorities report that by far the Nation's greatest need for hospital beds continues to be in mental hospitals, on the basis of currently accepted standards. A solution to this crucial bed shortage becomes even more compelling in view of the prediction by mental health authorities that one out of every 10 persons will spend some part of his life in a mental hospital, if current patterns of admission to mental hospitals and current death rates remain constant. This means that about 17 million persons now living in the United States will be hospitalized for mental illness at one time or another, unless new techniques of treatment and cure are developed.

But the committee found that although the seriousness of the bed shortage is unquestionable, the problem will not be resolved by simply meeting the need for hospital beds. Indeed, some facility planners even question whether any additional beds are required until the Na-

tion's entire mental illness picture is thoroughly examined and reevaluated. They believe that broad-scale decisions should await the results of a study of the nature and availability of the physical facilities needed for a comprehensive program of treatment and care. Some authorities even question the formula of 5 beds per 1,000 population, which is now used as a guide in determining the number of beds needed in mental hospitals.

The committee pointed out that in view of new treatment methods, facility requirements may take on a completely new dimension. As an example, it was noted that many senile patients might be transferred appropriately to nursing homes and the beds they now occupy could be used by the mentally ill in need of special hospital care.

The current trend of general hospitals "to become more general" by providing care for the mentally disturbed was commended by the committee. It was stated that this trend should be encouraged since a mentally ill patient when admitted to the general hospital receives therapeutic care at a time when such care is most important. Also, from the standpoint of social attitudes, many mentally disturbed patients would be less reluctant to enter a general hospital than a mental institution.

As of January 1960, Hill-Burton State agencies reported a total of 542,000 mental hospital beds throughout the Nation. This figure includes beds in mental hospitals and in psychiatric units of 10 or more beds in general or tuberculosis hospitals, but does not include beds in Veterans Administration hospitals, Public Health Service hospitals, and other Federal facilities. Of this number, some 92,000 beds, or 17 percent, were designated as unsuitable by the State agencies. On the basis of a more inclu-

A preliminary summary of the results of cytological examinations on 600,000 women indicates the efficacy of widespread use of cytology to detect cancer of various organs.

Uterine Cytology

RAYMOND F. KAISER, M.D., MARY M. BOUSER, R.N.
SAMUEL C. INGRAHAM II, M.D., and ALBERT W. HILBERG, M.D.

THE USE of exfoliative cytology to detect cancer of the uterus is now accepted in many areas of this country. Eight years ago, only a few thousand women were receiving an annual uterine cytology examination. Now it is estimated that each year more than 3 million women receive cervical cancer examinations using the cytological method.

The recognition of exfoliative cytology as a practical means of detecting early cancer of the uterine cervix was preceded by years of research. Among those groups responsible for the widespread acceptance and employment of the technique is the National Cancer Institute, whose investigators have pioneered in the application of cytology to detection of human cancer in large population groups.

The institute was one of the first agencies to recognize the potentialities of the cytological work of Papanicolaou, Trant, and others whose reports had been largely overlooked by pathologists and clinicians until after World War II. At that time, institute investigators

were evaluating a number of cancer "tests" described in the literature, and the cytological method was one of the few that appeared to merit further investigation.

In 1947, scientists of the National Cancer Institute established a study at Hot Springs, Ark., to evaluate the cytological technique as an aid to diagnosis of cancer of the uterine cervix. In the process of testing the method on women admitted to the venereal disease center, the investigators satisfactorily resolved many problems relating to the administration of such projects and provided some direction to basic problems of human cancer which may be studied using exfoliative cytology. On the basis of this experience, 4 years later the institute moved the project to Memphis, Tenn., to determine the practicality of vaginal cytology as a general population study procedure and to gather epidemiological information.

Preliminary data encouraged the establishment and operation of several other uterine cytology projects in order to develop new methods and techniques, investigate pathogenesis, and improve epidemiology procedures. These were set up at Columbus, Ohio; Louisville, Ky.; Madison, Wis.; New York, N.Y.; Philadelphia, Pa.; San Diego, Calif.; Washington, D.C.; Providence, R.I.; Detroit, Mich.; and Charlotte, N.C. Some of the projects have been directly administered by the institute, while others have been operated through grants to universities and medical schools. In each

Fewer Resident Patients of Public Mental Hospitals

The number of resident patients in public mental hospitals in the United States decreased during 1959, for the fourth consecutive year, according to statistics from the National Institute of Mental Health, Public Health Service.

At the end of the 1959 calendar year, there were 542,721 patients in 277 hospitals, 2,142 fewer patients than at the end of 1958. This decrease of 0.4 percent compares with a decrease of 0.7 percent during 1958, 0.5 percent during 1957, and 1.3 percent during 1956.

While the decline each year has been slight, it reverses a decided upward trend that had prevailed through this century. Between the years 1903 and 1951, the public mental hospital population quadrupled from 133,000 to 518,000. During the same period, the general population only doubled. The upward trend continued until 1956. Since then there has been a steady slight decline in the number of patients at the end of each year, even though the number of admissions during the year has continued to rise. Total admissions increased by 4.3 percent, 4.8 percent, 7.7 percent, and 6.5 percent in 1956, 1957, 1958, and 1959, respectively.

During 1959, there were 167,607 discharges as compared with 156,352 in 1958, an increase of 11,255 or 7.2 percent. In the three previous years, the number of discharges had increased by 11.8 percent in 1956, 8.9 percent in 1957, and 7.7 percent in 1958. The percentage change in the number of deaths as compared with the previous years was 8.6 percent in 1956, -2.9 percent in 1957, 9.5 percent in 1958, and -3.2 percent in 1959.

Commenting on the findings, Dr. Robert H. Felix, Director of the National Institute of Mental Health, pointed out that many factors are involved in these figures. It is unsafe to draw specific conclusions from them, he said, but they undoubtedly reflect a prevailing improvement in the care and treatment of the mentally ill both in and out of mental hospitals. He attributed this improvement, in part, to a basic change in the philosophy governing hospital administration and treatment in the past few years, and also in the public attitude toward mental illness. No longer is the hospital viewed as a custodial institution, he said. Its function is seen as rehabilitating the patient so that he can return to community living. Communities are assuming more responsibility and are providing preventive and rehabilitative services that help keep people out of mental hospitals.

Dr. Felix also credited new and improved treatment methods, including the wide use of psychoactive drugs, to the increased use of psychiatric beds in general hospitals, and to outpatient psychiatric clinics and other community facilities such as nursing homes, halfway houses, and sheltered workshops. He noted that 20 years ago, there were only 48 general hospitals treating psychiatric patients. Today there are some 500 with psychiatric units and many others that accept mentally ill persons for short-term treatment. Altogether, 1,000 or more general hospitals accept mentally ill patients. There are about 1,400 outpatient clinics offering psychiatric service within communities.

invasive carcinoma. Certain fundamental questions concerning this relationship have been summarized previously (1):

- Do all invasive cervical cancers begin as intraepithelial lesions?
- What proportion of intraepithelial lesions progress to invasive lesions?
- What is the time required for an intraepithelial lesion to progress to invasiveness?
- Do some intraepithelial lesions regress and disappear spontaneously?
- Is it possible for an intraepithelial lesion to remain noninvasive indefinitely?
- What are the age-specific incidence and prevalence rates of carcinoma-in-situ and invasive carcinoma?

Table 3, which is compiled from published material, shows considerable variation between studies in the proportion of intraepithelial and invasive cervical carcinomas found at first examination. Further analysis may reveal that this variation is due to different epidemiological factors in the separate study groups.

The women screened in the Madison study (2) were predominantly rural residents examined by their private physicians. The group was comprised of women 20 years of age or over, and included only a few Jewish or Negro women. The investigators suggested that the particularly high prevalence rates for invasive cervical cancer in Madison indicated that the physicians taking the smears were selecting women with suspected lesions. They reported, however, that the more recent trend has been to examine larger numbers of asymptomatic women, with a concomitant decrease in the percentage of total malignant tumors detected and a relative increase in the number of intraepithelial carcinomas discovered.

The study group in Hot Springs (3) included females in the cancer-age group who were admitted to the venereal disease center. The minimum age was sometimes 35, sometimes 40, in this study, and the study group was 93 percent Negro.

Dunn and his associates (4) reported that over two-thirds of their study group were patients of gynecologists and obstetricians, and the remainder were examined by other private physicians in metropolitan San Diego. The minimum age was 15 years, and relatively few

women over 50 were examined. The women were white and gentile.

In Columbus (5), 73 percent of the study group were examined by private physicians; the remainder were examined in various clinics. In their preliminary report, Ullery and his co-workers did not discuss age or race, except to state that the minimum age was 20 years.

Erickson and others (6) reported that their study patients, all 20 years of age or older, were examined in health department and hospital clinics, or in temporary clinics set up in industrial and business concerns, or by physicians in private practice. Approximately 13 percent of the women examined were not residents of Shelby County, the designated test area, but were women who came to Memphis physicians for medical care and were therefore a selected group such as will be found in any hospital sampling. Of the 373 women with invasive uterine cancer, 36 percent were nonresidents. However, the rate of occurrence of intraepithelial carcinoma was similar for residents and nonresidents, as would be expected for an asymptomatic, unsuspected lesion. The authors also found that whereas one-third of the surveyed population were Negroes, two-fifths of all the intraepithelial carcinomas found were among Negroes.

Rate Comparisons

The Memphis study produced a casefinding rate 40 times that observed in the community

situation there has been a high degree of cooperation with local health and medical groups and with individual physicians and pathologists.

The goal of the program is the cytological examination and evaluation of no fewer than 700,000 women tested once, 210,000 tested a second time, and 70,000 tested three times. It would be preferable, of course, to reexamine a larger percentage, but experience to date indicates that 30 percent is the best yield that can be expected on return examinations. At present, more than 600,000 women have been examined at least once.

A Single Research Experience

Although the women studied represent a number of widely separated population groups, certain uniform procedures and standards make it possible to view the entire group as a single research experience.

In all cases, the fixation and staining of the slide material have been accomplished by using the Papanicolaou technique. Examination of the smears for malignant cells or for evidence of abnormal cellular changes has followed the procedure originally established at Memphis. This system, referred to as a "pyramid," features step-by-step screening of smears by increasingly competent and experienced technicians, and final interpretation of suspicious smears by a pathologist.

All the projects have employed a standard code system of reporting data to a single evaluation center. The coded information includes patient identification, cytological examination and biopsy results, clinical or surgical findings, and data necessary for proper clinical evaluation and epidemiological study. In order to assay epidemiological factors in cancer of the uterine cervix, a record has been made of each patient's age, race, geographic location, marital status and pregnancy history, socioeconomic status, and ethnic or religious status.

There are, of course, some variations in procedure. The techniques for obtaining material for cytological examination include vaginal aspiration, cervical scraping, and cotton swab wiping, accomplished by using glass or plastic pipettes, plastic "straws," or wooden spatulas

or applicators. The specimens were collected by physicians, nurses, or medical or nurses' aides.

Some of the Findings

Thus far, 608,200 women have been examined the first time. Their laboratory smear reports are indicated in table 1. The designation "unsatisfactory" may refer to insufficient material on the smear, inadequate staining, loss of material, or breakage of the slide before interpretation. "Negative" smears are considered totally negative for cancer, and "atypical" indicates those smears that are negative for cancer but indicate some sort of epithelial cell abnormality. "Suspicious" means the smear shows some cells which may indicate the presence of cancer. Finally, "positive" indicates definite evidence of cancer.

By using raw, unpublished data, it has been possible to compute gross rates for various kinds of cancer found in the first examination of the entire group (table 2). Consideration of the number of intraepithelial cancers of the cervix compared with the number of invasive cancers of the cervix may shed some light on the relationship of intraepithelial carcinoma to

Table 1. Results of first cytology examination of 608,200 women

Result	Number examined	Percent
Unsatisfactory.....	5,660	0.9
Negative.....	578,640	95.2
Atypical.....	18,430	3.0
Suspicious.....	4,010	.7
Positive.....	1,460	.2
Total.....	608,200	100.0

Table 2. Proved cancers detected as a result of first cytological examination of 608,200 women

Type of uterine cancer	Number patients	Rate per 1,000
Intraepithelial carcinoma of cervix.....	1,490	2.45
Invasive carcinoma of cervix.....	910	1.50
Cancer of corpus.....	130	.21
Cancer of other sites of female reproductive tract.....	55	.09

Therefore, the scientists concluded that their method seems to fulfill the requirements of a practical procedure for processing samples of blood containing tumor cells found in individual patients affected with various types of cancer. Further study (8) established that a high percentage of cancer patients have malignant cells that appear to be viable circulating in the bloodstream. The authors noted that their results suggest that examination of peripheral blood may be justified for the establishment of a primary diagnosis of cancer in suspected cases that have eluded diagnosis by other means. The technique may also be of value in following patients after operation to indicate the presence of unsuspected metastases and in determining if manipulation of a tumor at the time of operation actually causes a "spraying" of malignant cells into the bloodstream. Further evaluation of the method is in progress.

Cytology is also being applied toward the detection of cancers of various specific sites other than the cervix, particularly the lung, genitourinary system, and gastrointestinal tract.

Considerable work is being done on the cyt analyzer (9), an electronic device designed to speed the examination of specimens obtained in the cytological test for uterine cervical cancer. This instrument has been found capable of accurately selecting a significant percentage of specimens that need not be examined further by cytotechnicians or pathologists. Research to improve its operation goes forward steadily. Emphasis is being placed on improving its accuracy and making more of its operations automatic with such developments as a self-focusing device and a mechanical slide feed, now in the research stage. It seems likely that the cyt analyzer can be modified for use in the examination of cytological specimens obtained from other parts of the body.

Summary

Exfoliative cytology has gained a wide and favorable reputation as a means of detecting cancer of the uterine cervix.

The National Cancer Institute continues a vigorous cytology research program, aimed at gathering information on the natural history of uterine cancer, use of cytology in the study of malignant cells in circulating blood, and perfecting methods of applying cytology to the detection of cancer of other body sites, such as the lung, genitourinary system, and gastrointestinal tract.

prior to the establishment of the project. Among the 108,136 women examined the first time, 60.4 percent, or 463 of the 766 cases of invasive uterine and intraepithelial cervical carcinoma found, were unsuspected. Of the 393 cases of intraepithelial carcinoma, 90 percent were unsuspected; 30 percent, or 112, of the 373 cases of invasive carcinoma were unsuspected. In addition, 20 cases of extrauterine genital cancer were found. These cases are not included in this analysis.

In Columbus, of the 99 patients found to have cancer of the genitalia—intraepithelial and invasive cancers of the cervix, and cancers of the corpus uteri, vagina, and ovary—69 percent had cancers that were previously unsuspected.

The Madison investigators reported that 74 percent of the confirmed cases of intraepithelial cancer of the cervix were not clinically detectable. The opposite relationship was evident for invasive cancer; that is, 73 percent were clinically suspected.

Table 4 compares the casefinding rates reported for first and second screenings in Memphis, Madison, and San Diego. Erickson and his associates reported that of each 1,000 women examined in the first screening, 3.6 were found to have intraepithelial carcinoma and 3.4 invasive cancer of the cervix. In the second screening, of each 1,000 women, 2.2 had intra-

epithelial carcinoma and 0.3 had invasive cancer of the cervix. The investigators suggested that adjustments for age and race differences in the two groups would probably show even greater reductions in casefinding rates. It is reasonable to expect that such adjustments in the Memphis data, and similar adjustments in the data for Madison and San Diego, would help to clarify the relationships between intraepithelial and invasive carcinoma.

Other Research in Cytology

The Cancer Institute's vigorous cytology research program is aimed not only at gathering much needed information on the natural history of uterine cervical cancer, but also at investigating other promising applications of the cytological technique.

A group of institute scientists have described a technique for preparing human whole blood so that it can be examined cytologically for the presence of malignant cells (7). They had previously become aware of the importance of determining whether cancer cells circulate in the peripheral blood of individuals some time before metastasis or generalized spread occurs. Such a finding might be highly valuable in cancer diagnosis or in predicting whether or not an individual cancer would be likely to spread.

Table 4. Comparison of uterine cancer rates in first two examinations

Project and examination	Number examined	Intraepithelial carcinoma		Invasive carcinoma	
		Number	Rate per 1,000	Number	Rate per 1,000
<i>Memphis</i>					
First.....	108, 136	393	3. 6	373	3. 4
Second.....	32, 728	72	2. 2	9	. 3
<i>Madison</i>					
First.....	65, 163	206	3. 2	335	5. 1
Second.....	9, 111	10	1. 1	4	. 4
<i>San Diego</i>					
First.....	33, 746	265	7. 8	78	2. 3
Second: ¹					
Class 1.....	9, 109	23	² 1. 6	2	. 2
Class 2.....	616	11	² 13. 8	0	. 0

¹ For second examination, women were classed 1 or 2 according to the results of their first examination. Classes 1 and 2 indicate that the women showed no changes suggestive of cancer in the first examination and that tissue studies were not recommended.

Murine Typhus Investigations in Southwestern Georgia

G. J. LOVE, M.P.H., and W. W. SMITH, Ph.D.

EFFORTS to control murine typhus fever in the southeastern United States, although overshadowed by accomplishments in the control of malaria, have achieved results which are almost as spectacular. An outstanding reduction of murine typhus transmission was accomplished within 25 years after the role of the rat and rat flea as host and vector of murine typhus was first suggested by Maxcy in 1926 (1) on the basis of epidemiological studies in Alabama and Georgia and validated in 1931 by Dyer, Rumreich, and Badger (2), who isolated the pathogen from fleas collected from wild rats.

The introduction of DDT, an insecticide with prolonged residual toxicity, into typhus control programs in 1945 and of anticoagulant rat poison in 1947 provided the tools with which the control of murine typhus was finally accomplished (fig. 1).

Incidence of the disease always has been greatest in the southeastern section of the country (fig. 2). Reported cases from 10 of the southeastern States rose from 1,799 in 1940 to 5,292 in 1944. Studies by Hill and co-workers

(3,4) indicated that probably at least two-thirds of the cases were not reported at that time, although by 1953 Quinby and Schubert (5) indicated that the trend may have been reversed, and the disease was being over-reported.

In Georgia, the number of reported cases of murine typhus rose from 57 in 1929 to 1,092 in 1937. Incidence of the disease was particularly high in the southern part of the State. By 1937 the disease had reached such proportions that a control program was initiated by the Georgia Department of Public Health (6). This program entailed elimination of harborage and food for rats and extermination of rats by trapping, poisoning, and rat-proofing of buildings. While these early programs were effective in localized areas, the total number of cases reported in the State rose to 1,135 in 1939, and 1,111 cases were reported in 1945 (fig. 3).

Bowdoin and Boston (7) stated that from 1932 to 1939 the greatest problems in the control of murine typhus in Georgia occurred in towns and villages and were associated chiefly with the business areas, particularly grocery stores, feed stores, and meat markets. However, beginning in 1945, shortly after Davis (8) demonstrated that DDT would control rat fleas, control programs using this compound so successfully disposed of these problems that by 1948 nearly 80 percent of 142 cases investigated in Georgia occurred in rural areas (9).

With the advent of DDT dusting, it was foreseen that the precise effect could be meas-

Mr. Love and Dr. Smith were formerly with the Emory University Field Station of the Communicable Disease Center, Public Health Service, at Newton, Ga. Mr. Love, currently on leave from the Public Health Service, is attending the University of Pittsburgh Graduate School of Public Health. Dr. Smith is an assistant professor of entomology and assistant supervisor of pest control with the University of Florida, Gainesville.

Signs

and

Symptoms

of trends in public health

A project aimed at promoting "more, and less frantic, speech making" was put into effect recently in Iowa. Under a new plan of the State Department of Social Welfare, materials prepared by staff for community interpretation will be swapped between State and county offices on a continuing "circuit" basis. Members of the department who are willing to share public interpretation materials which they have prepared are asked to send them in to the State office for mimeographing and distribution to county departments. The material so disseminated may be used in developing new talks or articles or verbatim, if it fits the occasion and time is pressing.

" "

Recent acquisitions of literature in the Chinese language at the National Library of Medicine include: photolithographs of ancient medical classics; herbals and collections of prescriptions and formulae for medicinal herb preparations still in common use; works, both ancient and modern, on acupuncture and moxibustion; popular handbooks and guides to basic health rules and practices in hygiene; and monographs on Western medical and pharmaceutical practice.

The relatively high proportion of material in the first and third categories reflects Peking's policy of "rectification of the erroneous attitude of slighting traditional medicine" and strengthening "the unity of traditional and Western style doctors . . . [to] . . . set in motion joint efforts in studying and systematizing traditional medicine" (*Chinese Medical Journal*, 79: 213,

1959). Works written as early as the Han Dynasty (206 B.C. to 220 A.D.) have been reproduced intact in some instances, and in others they have been re-edited, annotated, translated into colloquial language, or clarified through commentaries. The large amount of material on medicinal herbs reflects the intensive effort to domesticate wild herbs for large-scale cultivation to meet current requirements.

Monographs dealing with Western medical practice, aside from translations of English, Russian, and Japanese works, are predominantly basic, clinical discussions of infectious and communicable diseases. Little has been received concerning cancer, heart disease, poliomyelitis, or psychiatric disorders.

" "

About 87 million Americans have had at least one shot of polio vaccine and 68 million have had three or more injections, according to December estimates by the Public Health Service.

Among persons under 40 years of age, more than 34 million, or almost 30 percent, have had no vaccine. Among children under 5 years of age, the group that accounted for 43 percent of the paralytic cases this year, 4.5 million have had no vaccine.

" "

Connecticut has amended its public laws to permit special educational training or privileges to emotionally handicapped children (Public Act 664). Previously, this special treatment was confined to children between 4 and 21 years of age with a diagnosed physical or mental handicap.

At the 1960 annual meeting of the Health Physics Society in Boston, Secretary of Health, Education, and Welfare Arthur S. Flemming will speak on the responsibilities and activities of the Federal Radiation Council at a dinner session June 30. The 3-day session, beginning June 29, will also include a symposium on the effects of recommendations of the National Committee on Radiation Protection and Measurements on the interests and activities of labor, law, medicine, and insurance.

" "

In 91 hospitals in New York City with approved training programs during 1959, 48 percent of the interns and residents were graduates of foreign medical schools. One-fourth of the 9,254 interns and residents in 821 American hospitals were in New York. In 11 of New York's municipal hospitals, not one intern or resident was a graduate of an American school.

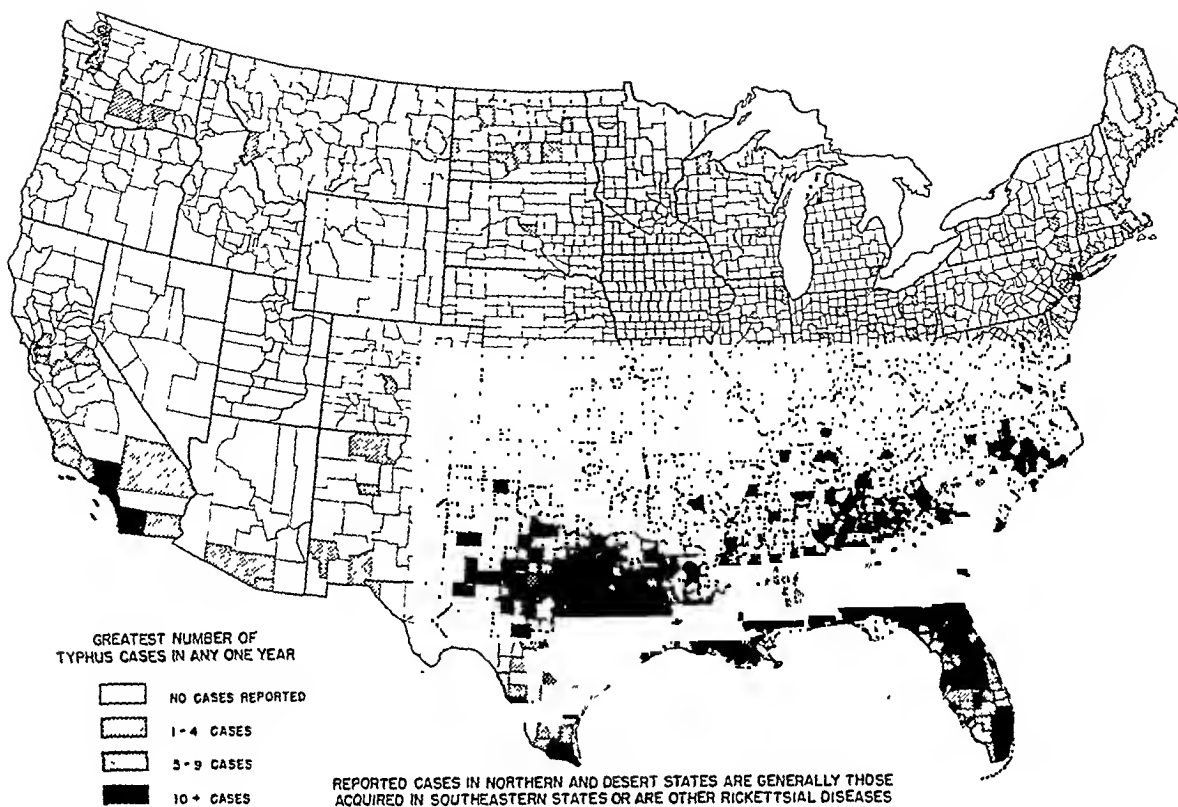

" "

Age and alcohol were significant factors in pedestrian fatalities in New York City in 1959. A study of 50 persons killed by automobiles while walking in Manhattan showed the average age of the victims was 59, one-half were born outside the United States and unmarried, and about three-fourths of those who died within 6 hours after an accident had been drinking. These and other findings of the study conducted by the driver research center of the New York State Department of Health in cooperation with other sponsoring groups were presented at the New England sectional meeting of the American College of Surgeons.

" "

Forty persons have been hospitalized in Chicago, Ill., for treatment of lead vapor inhalation; all but three were children. After two of the children died, the Chicago Board of Health ordered a wholesale drive against use of discarded storage batteries as fuel in space heaters and furnaces. Police reported four piles of discarded batteries had been found in vacant lots in the southside residential area of the city, where the victims lived.

Figure 2. Reported cases of endemic typhus in the United States, 1941-47

norvegicus prior to dusting was not measured, since relatively few rats in this species occurred in these counties at that time. However, in Thomas County incidence in this species was reduced from 28 percent in May 1946 to 6 percent in April 1948. In Grady County, incidence in these rodents ranged between 37 and 38 percent throughout this period.

This first study showed that good control was obtained for the oriental rat flea, *Xenopsylla cheopis* (table 1), and the mouse flea, *Leptopsylla segnis*. Control of the sticktight flea, *Echidnophaga gallinacea*, was erratic and little or no control of rat mites and lice could be noted. The study demonstrated decisively that murine typhus fever could be controlled with DDT.

The duration of control was studied between 1948 and 1950 (10, 11). Morbidity rates for human murine typhus continued to drop in the treated areas through 1950. In Thomas County, 69 cases occurred in 1945 in a population of approximately 34,000 people. This figure was

reduced to seven cases in 1947 and to two cases in 1949. Human murine typhus was not found in Thomas County through September 1950. In 1945, Brooks County had 35 cases in a population of approximately 16,000. In 1947 there were no cases, but two cases occurred in each of the years 1948, 1949, and 1950. Grady County, with nearly 17,000 population, experienced 46 cases in 1945, 28 cases in 1949, and 19 cases during the first 9 months of 1950.

Commensal rats collected during July and August of each year between 1948 and 1950 showed a constant infection rate of approximately 40 percent in Grady County. In Brooks and Thomas Counties, a consistent rate of approximately 10 percent was indicated. During this same period, the number of rats infested with the principal vector, *X. cheopis*, remained constant in Grady County at approximately 60 percent. In the dusted areas, infestation rates rose from an average low of about 4 percent in 1947 to about 30 percent in 1950.

Thus, during the 3 years following the typhus

ured accurately only by investigating the numerous factors which affect transmission of murine typhus. Accordingly, the Communicable Disease Center of the Public Health Service initiated studies on the control of the disease in support of State programs. The studies, conducted in several counties of southwestern Georgia, extended over a 12-year period from 1945 to 1957.

This report summarizes the information obtained from the investigations, compares the results from the various studies, and records conclusions concerning the control and possible eradication of murine typhus fever.

Typhus Control Program

The area selected for studying the effectiveness of DDT dusting comprised portions of Brooks, Decatur, Thomas, and Grady Counties in southwestern Georgia (fig. 4). Decatur County operations were discontinued before completion of the project. In Brooks and Thomas Counties, the control program was confined to DDT dusting of domestic rat runways, burrows, and other rat habitats. Grady County was used as an untreated check area. Control operations, consisting chiefly of five

applications of 10 percent DDT dust, extended from April 1, 1946, through September 30, 1947 (4).

The incidence rates per 100,000 population for human murine typhus, during the 18 months before dusting operations began, were 174 for Brooks County, 180 for Thomas County, and 232 for Grady County. During the first 18 months of the operational program, these rates were reduced to 14.7 for Brooks County and 31.5 for Thomas County, but remained rather constant at 236 in untreated Grady County (4). Data on annual incidence is given in table 1.

A similar reduction of the disease in commensal rats was shown by complement fixation tests on serums from domestic rats collected throughout the study (table 1). Tests on small samples of *Rattus rattus* collected prior to April 1946 revealed infection rates of 50, 63, and 46 percent in rats collected in Brooks, Thomas, and Grady Counties, respectively. Collections of this same species between May 1947 and April 1948 gave positive results on 3.4 percent of specimens from Brooks County, 7.4 percent from Thomas County, and 35 percent from untreated Grady County (table 1).

The incidence of murine typhus in *Rattus*

Figure 1. Annual total of reported murine typhus fever cases in the United States, 1932-57

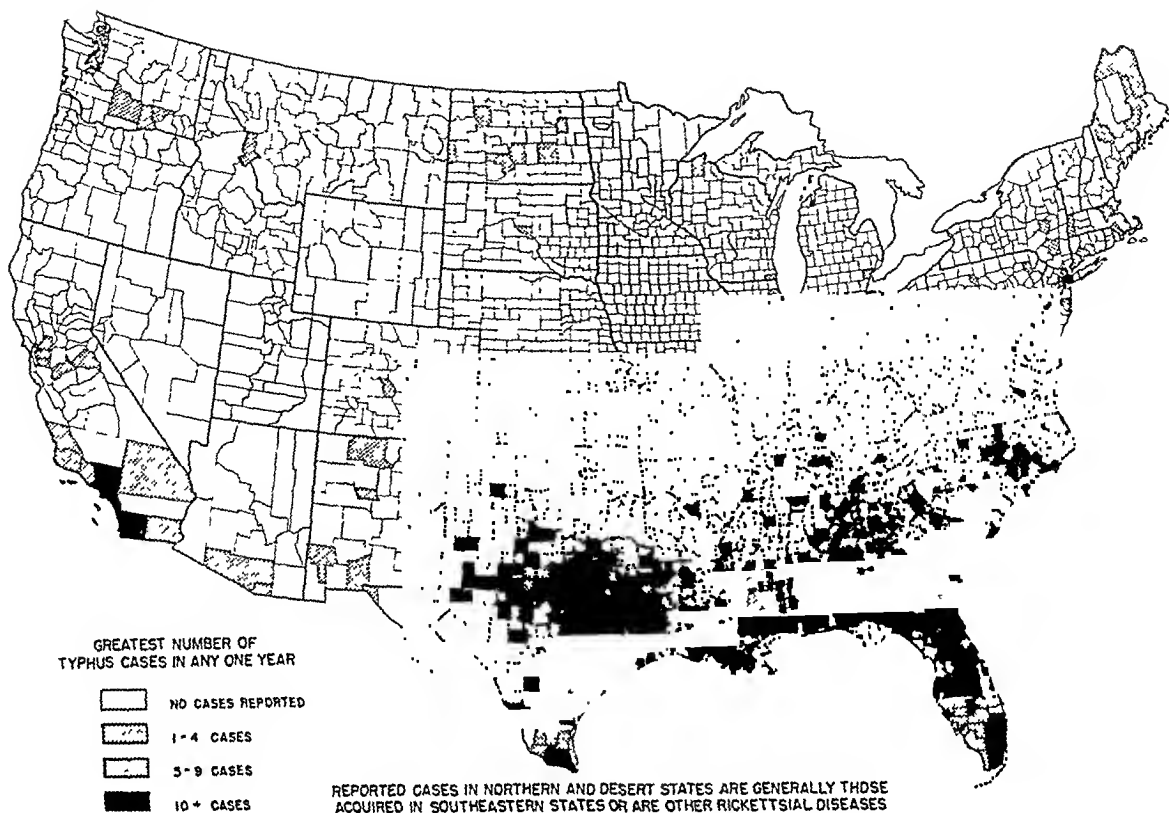

Figure 2. Reported cases of endemic typhus in the United States, 1941-47

norvegicus prior to dusting was not measured, since relatively few rats in this species occurred in these counties at that time. However, in Thomas County incidence in this species was reduced from 28 percent in May 1946 to 6 percent in April 1948. In Grady County, incidence in these rodents ranged between 37 and 38 percent throughout this period.

This first study showed that good control was obtained for the oriental rat flea, *Xenopsylla cheopis* (table 1), and the mouse flea, *Leptopsylla segnis*. Control of the sticktight flea, *Echidnophaga gallinacea*, was erratic and little or no control of rat mites and lice could be noted. The study demonstrated decisively that murine typhus fever could be controlled with DDT.

The duration of control was studied between 1948 and 1950 (10, 11). Morbidity rates for human murine typhus continued to drop in the treated areas through 1950. In Thomas County, 69 cases occurred in 1945 in a population of approximately 34,000 people. This figure was

reduced to seven cases in 1947 and to two cases in 1949. Human murine typhus was not found in Thomas County through September 1950. In 1945, Brooks County had 35 cases in a population of approximately 16,000. In 1947 there were no cases, but two cases occurred in each of the years 1948, 1949, and 1950. Grady County, with nearly 17,000 population, experienced 46 cases in 1945, 28 cases in 1949, and 19 cases during the first 9 months of 1950.

Commensal rats collected during July and August of each year between 1948 and 1950 showed a constant infection rate of approximately 40 percent in Grady County. In Brooks and Thomas Counties, a consistent rate of approximately 10 percent was indicated. During this same period, the number of rats infested with the principal vector, *X. cheopis*, remained constant in Grady County at approximately 60 percent. In the dusted areas, infestation rates rose from an average low of about 4 percent in 1947 to about 30 percent in 1950.

Thus, during the 3 years following the typhus

control operations, human incidence continued to drop, incidence in rats remained constant, and populations of the chief vectors increased.

Ecological Studies

The reduction of murine typhus in commensal rats as a result of the DDT dusting program led to speculation concerning the eradication of the disease through a concerted effort to eliminate both the vector flea by dusting and the rodent hosts by use of the newly developed anticoagulant poisons.

However, before appropriate techniques could be developed, it was necessary to gain thorough knowledge of the ecology of each group of organisms participating in the cycle of murine typhus transmission. Involved in the cycle are the pathogenic *Rickettsia*, the commensal rat reservoir, the possible reservoirs in other animal species, the ectoparasites which transmit the infection, and the susceptible hosts, either man or rodent, to which the infections are transmitted. Considerable

information concerning the ecology of these organisms was obtained during the course of the studies in southwestern Georgia.

Commensal Rats

In a study of the bionomics of roof rats Ecke (12) demonstrated a decreasing roof rat population from 1946 to 1951. The decrease was attributed to an increased mortality of young rats between the stages of parturition and trappable age. A survival period of 6 months or less for the majority of roof rats of trappable age was indicated by disappearance of 80 percent of marked rats within that time. Males disappeared more rapidly than females. Fewer than 1 percent were found to roam a distance greater than 500 yards, and movements between buildings more than 100 yards apart were rare. It was suggested that movements of greater distances resulted from mechanical transportation. Roof rats on premises that also harbored Norway rats had a greater tendency to move than those on premises where there were no Norway rats. Field evidence indicated that

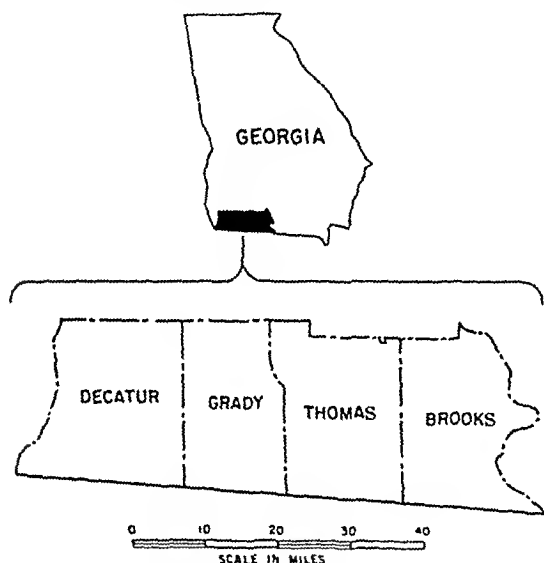

Figure 3. Annual total of reported murine typhus fever cases in Georgia, 1937-57

very few, if any, feral roof rats occur in southwestern Georgia.

The decline in commensal rat populations continued through 1956 (13). The incidence of infestations on farms in Thomas County dropped from 94 percent in 1946 to 35 percent in 1956. Studies indicated that although many ecological factors contributed to the decline, a series of drought years from 1949 through 1956 was apparently the most important factor. The scarcity of normal winter and spring rat foods, chiefly corn and peanuts, is believed to have affected the rat population adversely.

Figure 4. Location of typhus investigations in southwestern Georgia

In the three counties in which the typhus studies were being conducted, Ecker observed that between 1946 and 1951 Norway rats were constantly extending their range from north to south, invading roof rat territory (14). In 6 years the Norway rats over-ran about 1,000 square miles (fig. 5). The more aggressive Norway rats were able to exclude the roof rats from most of the infiltrated territory.

Melanism in the rat population of southwestern Georgia was reported by Smith (15). One hundred (19.1 percent) of the 523 Norway rats trapped alive in four counties of southwestern Georgia were black mutants. The high percentage of melanism indicates the probable inheritance of this character as a simple Mendelian

recessive. Black mutants were more prevalent southward of the advancing front of the invasion of Norway rats than elsewhere in the area. The mutants, it is believed, were chased out of the more stable colonies of normal Norway rats into roof rat territory where competition is less. Keeler (16) found that the black rats were much less aggressive than the Norways of normal color. There was no significant difference in the incidence of melanism in the sexes of the Norway rats trapped (18 percent of males black, 20 percent of females). No difference in the prevalence of typhus antibodies was noted between the normal Norways and the black ones (7.3 percent and 7.0 percent, respectively).

The effect of DDT dusting on commensal rats was studied by Dent and associates (17). They showed that the distribution of 10 percent DDT dust in rat habitats resulted in pathological changes consistent with DDT poisoning

Figure 5. Roof rat territory over-run by Norway rats, 1946-51

and in the accumulation of appreciable quantities of DDT and DDA in the livers and fat of exposed rats. In a treated colony of rats, 32.7 percent died within 7 weeks and 36.3 percent within 11 weeks, apparently from DDT poisoning. However, field observations indicated that such rates are in excess of those to be expected under natural conditions where rats can exercise greater freedom in avoiding unfavorable situations.

In a study of the ecology of commensal rats in relation to murine typhus, Morlan and associates (18a) observed that rats abandoned well-established, dusted runways in favor of new, undusted ones. They also suggested that fluctuations in rat populations on rural premises were more affected by the amount of food

available than by changes in climatic conditions. From a study of captive colonies of rats, they concluded that odor trails of established runways may be an important guide to rats. Measurement of more than 3,500 specimens determined the average body length of immature roof rats to be 124.3 mm. and for adults 165.9 mm. Average body lengths of Norway rats were 140.5 mm. for young and 206.3 mm. for adults. Reproductive activity for both species of rats centered around one peak in March and a lesser peak in August. In both species reproductive capacity was proportional to body length. The average titer level of positive serums from Norway rats was considerably higher than that for serums from roof rats, but there was no consistent difference in prevalence of typhus antibodies in the two species.

Ectoparasites

The ectoparasites of commensal rats in relation to murine typhus were studied by Morlan and associates (18b). Between May 1946 and April 1949, more than 20,000 rats were trapped and examined for ectoparasites. *X. cheopis*, *L. segnis*, *Ornithonyssus* (*Bdellonyssus*) *bacoti*, and *Polypylaw spinulosa* accounted for nearly 95 percent of the ectoparasites recovered. *P. spin-*

Figure 6. Seasonal abundance of the common ectoparasites of commensal rats as indicated by percent of rats infested (3-month moving average)

ulosa consistently infested a higher percentage of each species of rat than did any other ectoparasite. Rats which were positive to murine typhus complement fixation tests were more frequently infested with *X. cheopis* and *L. segnis* than negative rats. *X. cheopis* and *O. bacoti* infested young rats more frequently than adult rats. In an area without a murine typhus control program, *X. cheopis*-infested rats were found on between 80 and 90 percent of the premises from which rats were collected. Female *X. cheopis* and *L. segnis* predominated in samples of fleas taken. The proportions of female *X. cheopis* tended to increase in months with lower mean temperatures (60°-70° F.) and to decrease in months with higher mean temperatures (80°-90° F.). The seasonal prevalence of the most common ectoparasites of commensal rats is shown in figure 6.

Morlan (19) investigated the possibilities of adding either hydroxy-pentamethyl flavan or sulfur to DDT formulations in an effort to control effectively the tropical rat mite, *O. bacoti*, and the spined rat louse, *P. spinulosa*. Neither of these species was greatly affected by DDT dusting, but each of them transmitted murine typhus experimentally among laboratory animals (20,21).

A mixture of 8 percent DDT and 10 percent sulfur gave only slightly better control of the mite than DDT dust alone, and no appreciable reduction of the mite resulted from a mixture containing 8 percent DDT and 10 percent flavan. Neither of the mixtures significantly affected the spined rat louse.

Host relationships of arthropod ectoparasites were reported by Morlan (22). More than 506,000 ectoparasites were obtained from 32,320 mammals collected between October 1945 and April 1949. Twenty-eight host species yielded 7 species of *Mallophaga*, 7 species of *Anoplura*, 1 of *Hemiptera*, 3 of *Coleptera*, 5 of *Diptera*, 16 of *Siphonaptera*, and 66 species of *Acarina*. Small numbers of three additional host species were examined, but they were not infested. Forty-nine species of arthropods were collected from roof rats, 41 from Norway rats, 30 from cotton rats, 27 from opossums, 17 each from cottontail rabbits, gray squirrels, Florida skunks, and spotted skunks, 16 from cotton mice, 15 each from old-field mice, house mice,

and raccoons, 12 from foxes, and 11 each from little brown bats, fox squirrels, and domestic cats. The remaining 12 host species were parasitized by 10 or fewer species of arthropods. The seasonal abundance of several species of cotton rat ectoparasites is also reported.

Epidemiology

A review by Stewart and Hines (23) of 452 cases of murine typhus occurring in southwestern Georgia from January 1945 to January 1953 showed a seasonal peak of rural cases during the summer but an even distribution of urban cases throughout the year. Incidence rates were about twice as high in rural as in urban areas and about eight times greater in the white persons than in Negroes. Age-specific incidence rates were low in children, rising to a peak during the fourth and fifth decades. The mean titer of the Weil-Felix test was high during the first week of a murine typhus illness and then rapidly declined, whereas the mean titer of the complement fixation test reached a peak during the second week and remained high over the next 50-60 weeks, after which it slowly declined. When patients were treated with aureomycin, there was a consistent lowering of the mean titers for the complement fixation test, but very little effect on the Weil-Felix titers was demonstrated.

Eradication Program

In July 1953, efforts were begun to eradicate murine typhus from the southeastern quarter of Grady County, an area of approximately 130 square miles. Dusting of rat runs plus the distribution of maintenance of rat poisons (fig. 7) at all premises infested with rats continued through May 1954 (24). Commensal rats were eliminated successfully from 309 (88 percent) of 349 rural premises during the 9-month eradication period.

	Number of premises
Total premises inspected.....	713
Infested and treated.....	349
Infested and treatment refused.....	3
Not infested.....	361
Cleared of rats.....	309
Eradication incomplete.....	40

Figure 7. Distribution of rat poison during murine typhus eradication program in southwestern Georgia

Twenty-five percent of these cleared premises became reinfested within 1 year (table 2), and about 30 percent were, or had been, reinfested at the end of 2 years. The third year's inspection revealed that 40 percent of the cleared premises had been reinfested at some time.

At the end of the operational phase of the eradication program, *X. cheopis* fleas were found on 9 percent of 70 rats collected at the 40 premises where rat eradication was not successful. Three months later, no *X. cheopis* was found on 34 rats collected at 16 premises where rats had been eliminated but where reinfestation had occurred. One year later, examinations of 162 animals collected from all farms (61) in the eradication area where trapping appeared to be productive disclosed no *X. cheopis*.

At the end of 2 years, 142 rats were trapped from 42 premises where recent rat signs existed. Twelve rats (8.5 percent) had *X. cheopis* infestations. After 3 years 4.1 percent of 148 rats collected were infested with *X. cheopis*.

Positive complement fixation tests were obtained on 3 of 70 rats collected at the end of the operational phase of the eradication program from premises where rats were not eradicated. This indicated an incidence of slightly more than 4 percent in an area where murine typhus incidence in rats had averaged above 40 percent during the previous 9 years. Three of 34 rats collected from cleared but reinfested premises 3 months after eradication gave positive complement fixation tests. However, since these were adult rats it is believed they became in-

fested before the eradication program was completed.

Of 124 rats collected from 78 premises 1 year after eradication only 1 rat gave a positive complement fixation test. This rat was taken at the extreme periphery of the area and probably had migrated from an untreated area. Tests on serums from 138 rats collected 2 years after eradication measures ceased indicated previous typhus infections in 4 rats (2.9 percent) collected from 2 farms. One farm was on the border of the eradication area, while the other was well within. Neither had previously harbored typhus-infected rats. Three years after eradication, complement fixation tests of serums from 148 rats trapped at 66 premises were negative.

Effectiveness of Control and Eradication

Results of the DDT dusting program and the eradication program are not directly compa-

table for many reasons. The studies were not conducted concurrently, and environmental factors which affect rodent and ectoparasite populations were not consistent throughout the periods covered by the two studies. Both programs were highly effective, and the advantages of one over the other are speculative. In the dusting program, maximum effectiveness appears to have been obtained in approximately 1 year during which four dusting cycles were completed. Each cycle required about 3 months to complete, but because of the residual effectiveness of DDT it is doubtful that more frequent dusting would have produced better results. The operational aspects of the eradication program were completed in 9 months, but because of the climatic variations this difference of 3 months cannot be considered significant. It is probable, however, that a larger working force may have completed the eradication program in a shorter time. Since rat runs were dusted on both programs, the choice between the two must be made on the basis of the advantages of removing rats. At first glance, and certainly for immediate control, rat poisoning would appear desirable.

A program which produces such obvious effects as the removal of rats is readily accepted, although this acceptance usually takes the form of verbal encouragement rather than assistance. The majority of property owners cooperated to the extent of letting their premises be treated.

The poisoning of rats increases the activity of their ectoparasites and consequently increases the percentage which would contact a well-distributed residual insecticide. Also the reduction or elimination of rats provides far less opportunity for the multiplication of the small residuum of ectoparasites. However, from the viewpoint of controlling arthropod-borne diseases, the increased ectoparasite activity which accompanies rat poisoning may also increase the possibility that people will be bitten by infected specimens.

The dusting program effectively held ectoparasite populations at a low level for approximately 1 year after operations had stopped (table 3). Dusting once a year at the optimum time may maintain the ectoparasite populations at a low level in a rather stable commensal rat population. When both rats and ectoparasites

Table 3. Comparison of results of control and eradication programs

Program status	Dusting program		Eradication program	
	Percent of rats positive to complement fixation test	Percent of rats infested with <i>X. cheopis</i>	Percent of rats positive to complement fixation test	Percent of rats infested with <i>X. cheopis</i>
Preoperations survey	50.0	40.0	40.0	65.0
Operations suspended	4.0	12.5	4.3	9.0
1 year postoperations	4.0	4.0	.8	.0
2 years postoperations	7.0	20.0	2.9	8.5
3 years postoperations	10.0	30.0	.0	4.1

are removed, unless constant surveillance is maintained, premises become reinfested with rats which reintroduce ectoparasites from beyond the periphery of the control area.

In the typhus eradication area of Grady County, premises freed of rats became reinfested at the rate of 25 percent during the first year, 30 percent in 2 years, and 40 percent in 3 years. These data indicate that commensal rat populations probably return to former levels at a slower rate than would the ectoparasite populations when rats are not removed. Neither the dusting program nor the eradication program completely eliminated vectors or reservoirs of murine typhus. Subsequent to the dusting program serologically positive rats were reduced to 4 percent of the population. But as a result of the eradication program, the amount of typhus in the rodent reservoir, and therefore the source of infection for vector fleas, was reduced to a point where it was not detected.

Comparative costs of the two programs are again a matter of speculation. A thorough rat poisoning and dusting operation would require at least twice the time needed to complete one dusting cycle. Since labor is the major expenditure of such programs, the final expense could be twice that of the dusting program. This assumes, of course, that a single dusting cycle would successfully control the ectoparasites, a premise which is not indicated by the evidence. If two or more dusting cycles were found necessary, the costs of the programs should amount to approximately the same figure. The savings to residents of control areas resulting from the rat poisoning program may not be a considera-

tion in evaluating the effectiveness of disease control programs. But it appears that should two equally effective methods be available, the method of choice should be the one which yields the greatest overall benefit. The eradication-type program has three distinct advantages over the dusting program: greater reduction in the source of human infections with murine typhus, better acceptance by the public, and additional savings which result from the elimination of rats.

A third method of murine typhus control which has received some consideration is the elimination of rats by poisoning alone and omitting the DDT dusting to control ectoparasites. Such a program has exactly the same public appeal as the eradication programs, but has some serious deficiencies. Complete rat elimination was never accomplished in the experimental eradication area, and it is highly improbable that it can be achieved over sizable areas. In addition, infected vectors parasitic on the rats poisoned could remain in the area and constitute a hazard to man for many months. The additional expense involved in dusting rat runs concurrently with the poisoning operations is so small that its omission seems impractical.

Incidence in Other Feral Animals

The cotton rat, *Sigmodon hispidus*, appears to be the feral rodent most likely to establish itself in farm buildings where commensal rats have been eliminated. Its importance as a possible natural reservoir of typhus and the questionable ability of its chief ectoparasites to transmit the disease justified investigation (25).

Five hundred and twenty-nine cotton rats were trapped at monthly intervals from several locations in four southwestern Georgia counties from March 1956 to March 1957. Their blood serums were tested for murine typhus antibodies by complement fixation tests, and their ectoparasites were removed and identified. Only 1 cotton rat had a titer indicating previous typhus infection (1:128), while 15 other specimens exhibited lower titers. The most numerous ectoparasites were the cotton rat louse, *Hoplopleura hirsuta* Ferris, the mite, *Haemolaelaps glasgowi* (Ewing), and the cotton rat flea, *Polygenis (Rhopalopsyllus) gwyni* C. Fox. The peaks of abundance for the cotton rat louse, *H. hirsuta*, and the mite, *H. glasgowi*, coincided and occurred during late winter and early spring. The peaks of abundance for the flea, *P. gwyni*, were in February, April, and June. Based upon a comparison with earlier collections made in 1947-48 by Morlan and co-workers, an extraordinarily warm February in 1957 advanced the time of peak abundance in the case of each of the most numerous ectoparasites. The 5 species of fleas collected totaled 729 specimens; 11 species of mites, 7,108 specimens; 2 species of ticks, 10 specimens; and 2 species of lice, 6,360 specimens. Altogether 14,207 ectoparasites were collected, or 29 ectoparasites per infested cotton rat. Ninety-three percent (488) of the 523 rats had some ectoparasites. Higher percentages of cotton rats were infested by cotton rat fleas and *H. glasgowi* during a year with above-normal rainfall (1947-48) than in a dry year (1956-57), while the opposite was true for the louse, *H. hirsuta*.

The present importance of the cotton rat and its ectoparasites in the epidemiology of rural murine typhus is minor, but certain ecological and economic factors which favor possible increases may change the present situation.

Murine typhus in animals other than commensal rats was studied by Morlan and associates (26). Serums from 3,202 animals representing 37 species were tested by complement fixation, and 47 from 12 species were positive. Positive serums were obtained from the opossum, cottontail rabbit, fox squirrel, house mouse, rice rat, cotton mouse, old-field mouse, cotton rat, dog, Florida skunk, weasel, and blue jay. Samples greater than 100 specimens were obtained on

opossum, cottontail rabbit, house mouse, cotton mouse, old-field mouse, cotton rat, and Florida skunk. The percent of positive serums from these species varied from 0.5 for the cottontail rabbit to 2.7 for the cotton rat. Sufficient serum samples from gray squirrels, raccoons, domestic cats, and common hens were tested to indicate that these species are rarely, if ever, infected.

Summary and Conclusions

From 1945 to 1957 investigations of murine typhus were conducted in a four-county area of southwestern Georgia. During this period efforts were made to control the disease with DDT applied to rat runs and to eradicate the disease from a rural area by using both DDT applications and the anticoagulant rat poisons. In addition, a wide range of information was obtained on the ecology and vector-host relationships of ectoparasites and commensal rats and other mammals.

The investigations sought to determine the effectiveness of various methods used to control murine typhus, especially in rural areas. Although this purpose was fulfilled in considerable detail, the results obtained from the studies are significant from other aspects. First, it was shown that some commensal rat ectoparasites (*Xenopsylla cheopis* and *Leptopsylla segnis*) can be controlled by DDT dusting, while others (*Ornithonyssus bacoti* and *Polyplox spinulosa*) cannot. This information should be applicable to the control of any disease organism for which commensal rodents serve as the reservoir, particularly plague. The effectiveness of the programs extended for a considerable period following cessation of operations, indicating that periodic short-term operations would probably maintain the control of these diseases indefinitely. Commensal rat populations in rural areas, it was shown, can be controlled very effectively at a reasonable cost. While the elimination of rats is usually considered a part of environmental sanitation and the responsibility of the individual occupants of premises, the effectiveness of rat control is directly proportional to the size of the area freed of these rodents. For this reason, it would probably be advantageous to undertake rat elimination programs on at least a county-wide basis.

Cortisone and ACTH Impairment of Response to Rabies Vaccine

KENNETH F. BURNS, D.V.M., Ph.D., DOROTHY FRESENIUS SHELTON, B.A., JOHN M. LUKEMAN, M.D.,
and EARL W. GROGAN, D.V.M.

CORTISONE and corticotropin have been widely and successfully used in controlling human reactions to rabies vaccination, particularly the neuromuscular and anaphylactoid reactions induced by the rabbit brain tissue in the vaccine mixture. Although both drugs are used to control these reactions, this study may indicate that cortisone actually interferes with the production of immunity and thus defeats the objective of vaccination. ACTH, on the other hand, does not appear to significantly impair neutralizing antibody response to rabies vaccine, and would seem to be the drug of choice should the need for such treatment arise.

Interest in this problem was aroused when one worker in the Fourth U.S. Army Medical Laboratory was accidentally exposed while working with a rabid laboratory animal. He was given 11,000 units antirabies serum (refined and concentrated horse serum) and 0.5 milliliter modified Harris vaccine daily for 14 days. On the 7th day of the prophylactic regimen, urticarial and anaphylactoid reactions

(dyspnea) were observed and steroid treatment was instituted as follows: oral cortisone 300 milligrams daily from the 7th through the 14th days, with a gradual reduction in dosage and ultimate discontinuance of the drug on the 24th day (total dosage 4,200 mg.); intravenously administered hydrocortisone, 100 mg. on the 7th and again on the 9th day; Acthar Gel, 80 units per day from the 9th through the 16th days and 40 units per day from the 17th through the 25th days. By the 27th day, reaction symptoms were completely alleviated and the patient was discharged.

The patient (E.G.) exhibited a high level of circulating neutralizing antibody for a period of 21 days (table 1). The titer of neutralizing antibodies then fell rapidly, and even after 116 days, no evidence of active immunity, such as might have been expected from administration of Harris vaccine, was detectable. The time-titer relationship is compatible with passive immunity conferred by the prior administration of antirabies serum.

The normal response to rabies prophylactic treatment employing 14 daily doses of 0.5 ml. of rabies vaccine (modified Harris), administered subcutaneously was investigated by collecting serum specimens from five persons reporting to the emergency room, Brooke Army Hospital, with a history of exposure to the bites of rabid animals. Their serums were obtained at frequent intervals after initiation of prophylaxis (table 1). None of the individuals received antirabies serum at the time of treatment in the emergency room and none reported having received antirabies immunization at any

At the time of this study, the authors were working in the Fourth U.S. Army Medical Laboratory, Fort Sam Houston, Tex., where Lt. Colonel Lukeman was commanding officer and Mrs. Shelton remains as bacteriologist, Virology Division. Lt. Colonel Burns is assigned presently to the U.S. Army Chemical Warfare Laboratories, Directorate of Medical Research, Army Chemical Center, Md., and Major Grogan is now with the Walter Reed Army Institute of Research, Walter Reed Army Medical Center, Washington, D.C.

prior date. Neither ACTH nor cortisone was administered to any of this group. All five individuals demonstrated positive log neutralization indices ranging from 3.8 to 4.2 (table 1) when serums collected 18 to 21 days following initiation of therapy were compared with serums obtained before vaccination.

These results are to be expected from active immunization and strongly imply that the failure of the vaccine to immunize the first patient mentioned (E.G.) may well have been due to the concomitant administration of steroids. To investigate this possibility, animal experiments were undertaken.

Experiments on Animals

Rabbits were selected for this experiment, because much is known of their immunophysiology (1-5), particularly the role of the adrenal glands in immune reactions (6). Mature male Flemish animals weighing 3 to 4 kilograms were obtained locally and were allowed a

2-week period of acclimatization prior to initiation of the experiment. Throughout the study they were permitted a standard diet of rabbit chow ad libitum. A 16-hour fast was imposed prior to collection of serum samples.

Rabies vaccine (modified Harris), packaged for human use with 14 individual 0.5 ml. doses per box, was used. The Harris type vaccine is a living, attenuated virus, prepared by suspending in sterile distilled water the brains of rabbits that have been infected with attenuated (fixed) rabies virus.

A saline suspension of cortisone acetate (11-dehydro-17-OH-corticosterone-21-acetate) and corticotropin, ACTH (adrenocorticotrophic hormone, lyophilized), 40 international units per vial, reconstituted with 1.0 ml. of physiological saline on the day of injection, were employed.

Method

Thirty rabbits were divided into five groups of six each (table 2). Therapy was admin-

Table 1. Serum neutralization studies on human subjects receiving rabies vaccine

istered to each group as follows: group 1, rabies vaccine; group 2, rabies vaccine and cortisone; group 3, rabies vaccine and ACTH; group 4, cortisone; and group 5, ACTH. Two additional rabbits, designated as group 6 received no injections.

Groups 1, 2, and 3 received 14 daily doses of 0.5 ml. of a 1:10 dilution of the rabies vaccine. Injections were made subcutaneously in the cervical and scapular area. In view of the fact that the usual 20 percent Harris vaccine is given to adult and child alike in the same amount (0.5 ml.) and for the same number of scheduled doses (14), this dilution for rabbits

is approximately proportional by weight to an appropriate dose for an 80-pound child.

Cortisone acetate was given in 14 daily doses of 5.0 mg. each by intramuscular injection in the gluteal region. This dose is comparable to that given therapeutically to a 165-pound man. ACTH (20 I.U.), representing 50 percent of the minimal dosage recommended for control of drug sensitivities in adults, was given in the same manner. The ACTH dosage employed, although not pharmacologically equal to the cortisone dosage, is in excess of the physiological dose recommended for the rabbit.

All animals were weighed and bled from the

heart prior to inoculation and 15, 30, and 53 days after initiation of therapy. Neutralization tests were conducted according to the method recommended by the Commission on Viral Infections, Armed Forces Epidemiological Board, as quoted from Paul (7), with the exception that the second hour of incubation of the serum-virus mixtures was accomplished at 4° C. The neutralizing capacity of each serum was expressed as the log neutralization index, or the difference in log LD₅₀ end points of a given serum-virus mixture as compared with the appropriate pre-inoculation serum.

A serum was regarded as positive if the log neutralization index was 1.7 or greater. Those less than 1.0 were reported as negative, and results between 1.0 and 1.7 were considered equivocal. Rabies Challenge Virus Standard (CVS) was employed as the test virus. The rabies-fixed virus was supplied by Lederle Laboratories. Known positive and negative serums were included with each test for control purposes.

Results

Twenty-seven of the 32 rabbits used in this study survived an observation period of 53 days, and were included for serum neutralization studies.

All six of the rabbits receiving rabies vaccine alone (group 1) exhibited positive log neutralization indices (table 2). Of the six that received rabies vaccine and cortisone (group 2), five survived; four showed no significant immunity at the end of the observation period as measured by the neutralization test, and one had an equivocal neutralization index.

In contrast to these negative findings when cortisone was administered concomitantly with rabies vaccine, four of the five surviving rabbits that received ACTH and rabies vaccine (group 3) yielded positive antibody responses, while one was equivocal.

All rabbits that received cortisone or ACTH alone, as well as those not inoculated, exhibited no change in their immunological status. Mean log LD₅₀ titers for each treatment group indicate the depressing effect of simultaneous administration of cortisone with rabies vaccine and the minimal interference by ACTH, at the dosage employed (see chart). The antibody

Mean log LD₅₀ compared with CVS titers of rabbits receiving rabies vaccine (modified Harris) with and without simultaneous cortisone or ACTH

response in the group which received vaccine alone and that given vaccine along with ACTH falls in the positive category of criteria set forth by the Commission on Viral Infections

Discussion

Since steroid therapy is often indicated clinically to offset the various allergic and paralytic reactions rising from the administration of rabies vaccine, the question herein is of considerable practical importance. As indicated by observation of one human case and by animal experimentation, our results strongly imply that cortisone should be avoided when rabies vaccine is being administered, since it apparently interferes with the production of neutralizing antibodies.

The impairing effects of ACTH, on the other hand, appear relatively less harmful, at least in the doses employed in our experiments, and probably do not adversely affect developing immunity. According to our studies, ACTH does result in a somewhat lower titer of neutralizing antibodies than when vaccine alone is employed (group 3 compared with group 1), but four of five animals receiving this drug nevertheless de-

veloped sufficiently high antibody titers to fall into the positive category.

Kass and associates (8-10) were able to show that rabbits ordinarily produce corticosterone as the predominant secretion of the adrenal gland and, as ACTH is given, there is a progressive shift toward cortisol production by the adrenal. Thus, at varying dose levels of ACTH these authors were able to get different effects on the production of antibodies, correlating roughly with the expected production of cortisol. They were led, therefore, to postulate that corticosterone has less effect on resistance to infection and on antibody response than does cortisone.

Although direct extrapolation of the results from rabbits to man should not be made because of the alteration in endogenous steroid output after the use of exogenous steroids in rabbits (11), there is, nevertheless, a definite indication of the need for conservative use of cortisone in humans when administered simultaneously with rabies vaccine for control of allergic manifestations.

While cortisone and, to a certain extent, ACTH interfere with the immunizing properties of rabies vaccine, neither drug appears to affect passive immunity adversely. The persistence of rabies neutralizing antibody in circulation for as long as 21 days seems to indicate that neither ACTH nor cortisone therapy caused early destruction of the administered passive immunity.

There is no reason to believe that the suppression of formation of rabies-neutralizing antibodies by cortisone in these experiments was a specific or selective effect. Previous experiments in rabbits (12) have shown that such results represent a general depression of protein anabolism and hence of antibody formation. The present observations are probably explainable on the same basis.

Summary

The concomitant administration of cortisone and ACTH to a patient who was receiving rabies vaccine appeared to prevent the production of active immunity.

Further studies on rabbits showed that cortisone interferes with the active immunity ordinarily resulting from rabies vaccine. ACTH,

on the other hand, while slightly depressing titers, does not prevent the formation of neutralizing antibodies.

It would appear, therefore, that for allergic reactions requiring steroid treatment arising during the course of administration of rabies vaccine, ACTH is the drug of choice and that cortisone is contraindicated.

In the single human case studied, neither drug affected adversely the passive immunity conferred by the injection of antirabies serum.

Research: Challenge to Health Departments

PAUL Q. PETERSON, M.D.

MANY health workers have expressed concern over the disparity between the emphasis placed on medical research and application of the results of research in program activity. The reasons for this concern are easily understandable, and it should be made a matter of record that research administrators are also concerned with problems of dissemination of information and application of knowledge. Concern over a problem may be a good thing because it implies analysis, and understanding may result from the thinking that takes place during the process.

In any discussion of an issue, the principle involved should be clearly stated. Therefore, let me state that I think the evidence is quite clear that the health department's primary mission of service is accomplished best if it is based upon a firm foundation of basic research that has been applied to programs through carefully conceived developmental research. This being the case, it appears to me that the health department has a twofold role in research: one is primarily in epidemiological investigations, the other is in operational studies.

The health department's primary mission of service must not be jeopardized by any tangential activity, no matter how attractive. However, I would suggest that the professional stimulation that comes from participation in a

research endeavor will, in most instances, more than compensate for the time given to the research project. This is such a well-established principle in academic institutions that faculty time is programed to include research.

Another very significant aspect of this subject is the nature of research itself. According to the one definition, research is a "studious inquiry having for its aim the discovery of new facts and their correct interpretation." This, therefore, includes orderly observation of occurrences, the accurate recording of data, and the objective analysis of the information compiled. Every day in every health department with a program worth its salt, observations are being made routinely. However, most recording of these observations is designed to furnish administrative rather than scientific information. Only a few departments make a serious effort to analyze the data in their records, so much valuable information is lost in the files.

Yet public health is the specialty that created and refined epidemiology as a technique, a procedure, and a thought process. The one health organization in the best possible position to make professional observations on groups of people is the health department. Because some of the answers to the most pressing public health problems hinge on studies of the natural history of disease, the inevitable conclusion is that health departments have a vital contribution to make through research. Perhaps I should say investment rather than contribution, because research pays dividends.

Whether the disease be infectious or non-infectious, whether it be acute or chronic in

Dr. Peterson is assistant director of the National Institute of Allergy and Infectious Diseases, Public Health Service, Bethesda, Md. The paper is based on an address to the Ohio Health Commissioners Conference held at Columbus, Ohio, on September 10-11, 1959.

nature, longitudinal epidemiological studies represent the only presently known way in which a substantial part of the knowledge we must command can be marshaled adequately. The equation, as I see it, may be stated as follows: Medicine needs information that can come only from careful studies of the natural history of disease. The epidemiological method is the research system of choice. The health department, by tradition, training, position, and skill, should be better able to do this type of research than any other professional group.

I know that I am suggesting new responsibilities, but health departments have been challenged before. Their achievements are a matter of record. For example, the steadily increasing health problems of the aging and chronically ill have led Ohio health departments to forge ahead in this new field of health activity. "Programing in Long-Term Illness and Aging" was discussed at this annual conference 2 years ago. Since then some of the best diabetes programing in the country has been accomplished in this State. In addition, exploration with such new programs as glaucoma casefinding and meals-on-wheels has been carried out.

Continuing Responsibility

But the control of infectious diseases is a continuing responsibility. A few years ago Dr. Karl F. Meyer delivered the sixth R. E. Dyer lecture (1) at the National Institutes of Health and discussed the natural history of plague. He said: "For centuries, man's survival has been chaotically interfered with by the infectious diseases, in pandemic form, dramatically. In the last half century, man, through his intelligence and diligence, has begun to control this chaos effectively for the first time. . . . These advances are good cause for great rejoicing. They are not cause for believing that parasitism holds no further challenge to man's ingenuity. . . . Immunization . . . chemotherapy . . . both of these defenses, magnificent but temporary, leave the parasite free to carry on its usual latent existence untouched: to multiply, to adapt, and to exert its capricious effects on the hosts. . . . The ever-

lasting question, what forces create, maintain, and suppress epidemic diseases of man and animals, has never been fully answered."

That infectious diseases go through cycles is widely recognized. Plague reached catastrophic proportions during the Renaissance. Syphilis spread as an epidemic during the 16th century. Smallpox was the scourge of the 17th and 18th centuries. The bacterial diseases, such as tuberculosis, diphtheria, and scarlet fever, next came on the scene and began to recede only as late as the early part of the 20th century. Virus diseases, exemplified by the pandemics of influenza which have occurred in the last 40 years, are among our greatest causes of concern today.

One of the earlier and more specific statements expressing this problem was made by William Parr in 1873 in a letter to the Registrar General as quoted by Hirsch (2): "The infectious diseases replace each other and when one is rooted out it is apt to be replaced by others which ravage the human race indifferently whenever the conditions of health are wanting. They have this property in common with weeds and other forms of life, as one species recedes another advances."

Dr. Rene J. Dubos in his extremely thoughtful treatise, "Medical Utopias," writes (3): "In the field of infectious disease, we need not go far for examples because the future is already with us. While mortality from acute bacterial infections is at the all-time low, chronic disorders of complex and ill-defined microbial etiology loom larger and larger on the horizon."

Therefore, we may postulate that as the health profession solves one problem through research, this very advance may create new biological equations which require solutions. The genetic instability of infectious agents with reference to chemotherapy or to spontaneous mutations provides examples. Another variant is the changing pattern of reservoirs of infectious agents. As long as a potential agent of disease continues an uninterrupted natural cycle, it may remain nonpathogenic or only mildly invasive. However, the current mobility and numerical growth of our population, the substantial changes in domestic and wild animal

life moieties, the altered nature of land usage, and many other developments tend to disequilibrate these relationships. The result is a continuous "spinning off" of newly invasive agents which are disease producing to various degrees. This pattern of biological adjustment will probably go on indefinitely.

Man's only safety from natural or overt biological warfare is the lead time achieved by research. This lead is precarious. The recent emergence of staphylococcal strains, for example, marked by their communicability and virulence and by high resistance to antibiotics, is recognized in many hospitals as the most immediately urgent of all infectious disease problems (4). The resistance of the anopheline mosquito to insecticides is a major threat to success of worldwide malaria eradication programs (5).

In my opinion methods of control can be found for almost any pathological state, but we cannot be complacent. Disease agents will change through the adaptive reactions demanded by their environments. We must maintain a constant research effort to gain adequate knowledge about infectious agents and their ecology. We must be able to understand the manner in which men respond to the infectious challenges which continue to arise from the environment.

Advances in Microbiology

The National Institute of Allergy and Infectious Diseases has reported recent work that shows we are moving forward in our understanding of microbiology. The implications in terms of future public health programing can be envisioned.

In collaboration with the Children's Hospital Research Foundation and the Washington, D.C., Welfare Department, Dr. Joseph A. Bell and his associates have demonstrated an epidemiological technique for intensive, detailed study of respiratory virus infections in a small population. They have traced a panorama of so-called undifferentiated respiratory illness, such as those caused by adenovirus, Coxsackie virus, and others. These studies in nursery and hospital groups have aided in the definition of the place of a new microbial group, the myxo-

viruses, in respiratory disease. These newly recognized agents were found to have caused more acute upper respiratory disease in the study group than Asian influenza during the pandemic year 1957 (6).

In collaboration with the animal research services of the U.S. Department of Agriculture, Dr. Robert J. Huebner and Dr. Francis R. Abinanti have demonstrated that parainfluenza virus occurs extensively in cattle. Preliminary studies (7) show a relationship of this virus to costly bovine respiratory diseases, particularly shipping fever. This may be a lead to recognition of a new animal reservoir of infectious agents which cause respiratory disease.

Dr. Sarah Stewart, National Cancer Institute, Dr. Bernice Eddy, Division of Biologics Standards, and their co-workers revealed a filtrable agent associated with tumor formation in mice (8). Huebner, Dr. Wallace Rowe, and associates (9-11) have applied precise virological methods to this mouse polyoma virus and have characterized it immunologically. They demonstrated its excretion in saliva, urine, and feces of infected mice, established its spread among mice by respiratory and intestinal routes, and showed it to occur as a contaminant of numerous transplantable tumors. The observations are pertinent to study of possible virus etiology in human cancer.

Dr. Carl L. Larson, Dr. Edgar Ribbi, and co-workers of the Rocky Mountain Laboratory in Hamilton, Mont. (12), have reported a method for harvesting cell walls free of contamination with cellular protoplasm. Fractionation of tubercle bacillus cell walls suggests a more effective, less toxic immunizing antigen can be obtained free of material which causes delayed hypersensitivity.

Perhaps these examples of research represent studies too intensive or specialized for the average health department to undertake, but, as I have suggested, there is a need and a role for the health department investigator in medical research.

Applications for Grants

The application for a grant from the National Institutes of Health for research or training begins with the individual investigator. Thus,

as a basic policy, the subjects of study are not prescribed, but instead follow the interest of the scientists themselves.

The application should be sponsored by the investigator's institution, since decisions must be made as to the adequacy of the research facilities available. When a grant application is received by the Institutes' Division of Research Grants, it is assigned to 1 of 33 study sections. These are composed mainly of scientists from universities and medical schools. They assess the competence of the applicant and the merits of the proposed research.

Next, the application is considered in the light of the total research program of the institutes. The matter is then brought before one of the nine National Advisory Councils, composed of non-Federal leaders in science and public affairs. The councils have two functions: they review the actions of the study sections and make final recommendations to the Surgeon General of the Public Health Service, and they advise on general program policy questions.

Following council recommendations, the Surgeon General approves or disapproves the grants. If the decision is favorable, the Division of Research Grants handles the mechanics of payment.

So far as I have been able to determine, more professional and scientific people have participated in this program through membership on advisory councils and study sections than in any other medical research program in history. This broad participation by the scientific community is, we think, one of the great strengths of the extramural grants program.

In summary, it has been my purpose to describe the research grants program of the National Institutes of Health, to point out the health department's unique opportunity for productive research in the natural history of disease, and to explore the concept that infectious disease research today is prologue to the control measures of tomorrow. I am sure that great new challenges and opportunities for service lie ahead for the public health departments.

Noncoercive Campaign

Reduced consumption of wine in 1959, which had been steadily increasing since 1946, and a 25 percent drop in deaths directly attributable to alcohol marked the first victories in France's noncoercive campaign against alcoholism. It has been estimated that 10 percent of the men and 3 to 4 percent of the women are excessive drinkers.

The campaign against alcoholism has three major facets: a public appeal to promote moderation, increased sales of nonalcoholic drinks at reasonable prices, and the prevention of economic dislocation in a major industry.

For several years demographic specialists, physicians, and sociologists, under the aegis of the Alcohol Research and Information Council, an organization created by the office of the Prime Minister, have been working with services of the Ministry of Health; the Committee for Protection against Alcoholism, a voluntary organization; and the Social Security Service.

Studies in 1955 and 1957 revealed that 7 out of 10 Frenchmen believed that the campaign against alcoholism was necessary, but that aperitifs and spirits were to blame for the damage caused by alcohol. The public also honestly believed that an average of 2 or 3 liters of wine per day was reasonable consumption.

This has been termed a fallacy, for alcoholism in France is primarily a matter of wine drinking; 70 to 80 percent of the 30 liters of pure alcohol that the "average Frenchman of the statisticians" absorbs annually are in the form of wine. Therefore, the public appeal was aimed at moderation in wine drinking. The maximum quantities suggested were 1 liter per day for a heavy laborer, three-fourths of a liter for a less active worker, and a half a liter for a sedentary worker.

A measure of the success of the public appeal was the fact that 8 out of 10 people who had heard of the campaign understood correctly that its aim

was moderation, and half of these knew that a liter was the maximum quantity that should be drunk each day.

Other indications were more definite. Mortality rates from alcoholism decreased in 1958 after increasing 12 times from 1946 to 1956. Mortality rates from cirrhosis of the liver, which had increased six times over the same 10-year period, were 12 percent less. Consumption of aperitifs has been decreasing since 1952. Consumption of wine dropped 500 million liters between 1956-57 and 1958-59, and the trend is continuing.

Drinking of fruit juice, still relatively modest, increased 30 percent per year over the same period. The council announced that an important firm of fruit juice distributors was launching a campaign to sell grape juice at 25 cents a liter, and an important wine cooperative intends to market its own grape juice at a price not more than that of wine.

The economic effects of reduced consumption will have to be offset by increased exports of quality wines and spirits. It has been calculated that an 8 percent reduction of consumption of these better qualities within France would enable the profits from exports to be doubled.

Sleep Brigades

In Cabinda, a wedge of Angola north of the Congo River, five mobile groups called sleep brigades battle the scourge of sleeping sickness. Each group consists of a physician, 2 nurses, 21 microscope technicians, 10 sanitary workers, an administrator, 3 drivers, and 12 servants. In the period from 1949 to 1958 the number of persons with the disease dropped from 15,785 to 917. In some years 5,000 to 6,000 people were examined.

Sleeping sickness, which once dominated nearly 5 million square miles south of the Sahara, is receding. Although some regions are still deserted, the spread of the disease has been stopped as far as man is concerned. However, it still affects cattle; nagana, as it is sometimes called, hinders the development of cattle raising.

Infektsionnye Psikhozy

Infection Psychoses

T. P. SIMSON

The original article in Russian appeared in *Zhurnal neuropatologii i psikiatrii imeni S.S. Korsakova* (*Journal of Neuropathology and Psychiatry imeni S. S. Korsakov*), volume 56, pages 389-394, 1956. It was translated by the Russian Scientific Translation Program of the National Institutes of Health, Public Health Service.

IN the evaluation of the acute infection psychoses, Soviet psychiatrists adhere to the point of view that the character of the external influence is not immaterial to the structure of the pathological conditions which are combined under the name "exogenous psychoses" and that definite typical main syndromes are characteristic of various infections (1-3). However, it is becoming progressively more obvious that the characteristics of the clinical picture at various stages of the course of the process, chiefly during the initial period and during the final period of the disease, are of much greater significance in establishing the typical features of one infection psychosis or another.

At the height of the infection psychosis, when various phases of protective inhibition of the cerebral cortex are observed, the psychotic states induced by various infections are very similar.

Previously, Bonhoeffer's conception predominated abroad. There are certain disagreements between authors on the problem of pre-

disposition. Stransky, based on the Meinertian "amentiagrupp" nomenclature, combines the acute infection, the toxic psychoses, and even psychoses occurring on the background of somatic diseases and exhaustion in this group (4). Stransky sees no essential differences within this broad group, and if any are found they are determined, in his opinion, chiefly by the individual characteristics of the personality.

The condition known by the name of "acute delirium" (*delirium acutum*) has been attracting the special attention of both Soviet and foreign authors. A number of authors express doubt that this condition belongs to the schizophrenia group ("fatal" or "hypertoxic" schizophrenia). In the observations of Ageyeva, Arutyunov, and Slutskina (5), some of the patients with "acute delirium" had in the past had a mental disease; acute delirium occurred in the patients in a temporary association with the infection and was, in the author's opinion, an allergic reaction on a pathological background. Histopathological examination of the brains of patients who died from acute delirium showed that in the severe forms of this disease there are signs of long-existent pathology along with the acute changes (perivascular edema, hemorrhages, swelling of nerve cells): hyperplastic changes of the pia mater, thickening of the adventitia of the small vessels, hyperplasia of the glia; that is, two processes: a new one and an old one. The infection had acted on a pathologically altered background.

The opinion was expressed that psychoses which occur in connection with streptococcal, staphylococcal, colon bacillus infections, that is, with the ordinary "pyogenic" infections, correspond to the concept of "acute schizo-

phrenia" (6); these may show the picture of "acute delirium," which is erroneously taken for "acute," "very actively progressive," "fatal" schizophrenia. In patients with the picture of "acute delirium," hemolytic streptococci, staphylococci, and colon bacilli with pathogenic properties have been isolated from the blood and sometimes from the spinal fluid. In the presence of a fatal outcome the same microbes have been cultured from all organs, including the brain.

Belsanti distinguishes symptomatic acute delirium associated with definite known causes and essential delirium which is underlain by three factors—toxic, constitutional, and emotional (7). Both variants of "acute delirium" are associated with an inborn hyperactivity of the cerebrospinal reticular system. Essential delirium is distinguished from symptomatic delirium by the stormy course of the symptoms in the absence of infection or azotemia associated with the hyperproduction of gluco-corticoids which cause protein decomposition. Massive hemorrhages are found in the suprarenals; in the brain, slight inflammatory and acute degenerative changes. The author mentions the progressively increasing azotemia in cases of acute delirium, although in individual patients it may be absent.

On the basis of a study of the brains of 30 patients who died from delirium acutum, Bom emphasizes the importance of hyperactivity of the hypothalamus, which leads to exhaustion of this vitally important center (8). An increased vacuolization occurs in the paraventricular nucleus and supraoptic nucleus, and chromophobia is noted in the ganglion cells.

In the literature there are indications of the presence of a disseminated degenerative process in delirium acutum, chiefly in the area of the third ventricle, which is manifested in the form of small perivascular hemorrhages.

All the authors mentioned agree on the fact that in "acute delirium" the adaptive functions of the organism are impaired. Lingjaerde believes that in "acute delirium" we can speak of a psychosomatic process which is expressed in a reaction similar to a crisis in Addison's disease (9).

While justified in many cases of delirium acutum, the arguments of a number of authors

for the inflammatory nature of this disease do not necessarily eliminate the concept of a fatal schizophrenia.

Rozenberg has done considerable work in the study of the characteristics of psychoses in the chronic and latent infections (10,11). An analysis of the data of his observations on patients with conditions such as malaria, brucellosis, tularemia, rheumatic fever, and wound infections, has shown that chronic infectious psychoses are characterized by a distinct picture which approximates them to the so-called exogenous psychoses. Their course may be remittent, intermittent, or relapsing.

Repeated psychoses not uncommonly occur in the presence of a weak general somatic reaction; increase of the latter can sometimes eliminate the psychosis. The pathogenesis of these psychoses is complex; here, there are also allergic signs as a result of sensitization of the organism and weakening of the cerebral cortex under the influence of prolonged stimulation, which brings about an inadequate neural regulation of somatic processes in the organism.

The condition of the defensive mechanisms, the type of nervous system, the sensitization by a series of external, even if minimal, influences during the life of the patient are of particular significance in chronic infections accompanied by somnolence. According to A. Z. Rozenberg's observations, in those patients in whom anxiety-depressive, depressive-hallucinatory, depressive-hypochondriacal states, or paranoid or catatonic syndromes predominated in the picture of the psychosis, consciousness remained intact. Psychosis initially can be manifested in very acute pictures, can proceed subacutely, and finally, in a wave-fashion, gradually becoming quiescent; as a result of it, residual encephalitic states may occur.

The periodicity of the course may be explained, in the author's opinion, on the basis of N. S. Vvedenskiy's teaching of parabiosis. The summation of prolonged and weak stimuli leads to the periodic occurrence of parabiogenic inhibition. In the presence of an alternating course, contrasting states alternate: manic and depressive, stuporous and expansive. The author believes [it is hard to agree with this] that whereas the central nervous system shows a reaction in a somniferous infection, the somatic sphere is

apparently not involved; allergic reactions (such as blood changes and erythema) are distinctly expressed. Among the latent infections on the background of which psychosis has arisen, mention is made of osteomyelitis, malaria, brucellosis, and infection of unknown etiology.

Of 100 patients observed by the author, 42 became sick repeatedly, which attests to the marked change in their reactivity. Freezing, burns, bruises, and excitement contributed to the occurrence of the psychosis.

The author separates the chronic psychoses in latent infections both from schizophrenia and from manic-depressive psychosis, advancing such criteria as fatigability, somnolence, hallucinatory experiences at night, lability of the emotions, polymorphism of the clinical picture, etc.

By establishing the general rules and regulations of the course of psychoses in latent infections, A. Z. Rozenberg certainly does not deny the unusualness which various infections introduce into the clinical picture of psychosis. He mentions typical features proper to psychosis in chronic malaria, tularemia, rheumatic fever, tuberculosis, and suppurative infections.

A study of psychoses in infections of chronic course is being extensively carried out abroad. However, we have encountered almost no comparative evaluation of these psychoses from the point of view of the typical character of certain clinical pictures for one or another infection. This is demonstrated by the evermore considerable popularity of Bonhoeffer's concept.

Chistovich and his co-workers are trying to approach the problem of schizophrenia on the basis of a study of infections. The author believes that during psychoses in conditions such as brucellosis, rheumatism, and suppurative infections, it is possible for schizophrenic disorders to arise with transition into schizophrenic damage. The author has in mind grave chronic psychoses with the prolonged sluggish course of rheumatism in tonsillitis, in otogenous and postnatal infections (12), and in streptococcal and staphylococcal infections.

Chistovich (6,13,14) believes that the psychosis which develops in chronic infections, which represents "a model" of schizophrenia,

is in no way different from "the original"; that "fatal," "very active" schizophrenia is an acute toxic-infectious septic psychosis with a hyperergic reaction and the depression of all the defensive functions of the organism.

In Gruhle's work, "Symptomatic Psychoses," attention was given to the so-called "symptomatic" schizophrenias (15). The author distinguishes the following: exogenous diseases combined with real schizophrenia; diseases in which a latent schizophrenic process is shown; diseases in which a readymade syndrome of schizophrenic character is found in a disturbed personality; diseases producing schizophrenic symptoms.

The author believes that only in the last case should we speak of symptomatic schizophrenia. We can hardly agree with these views.

Of the various infections to which considerable attention has been given in recent years, rheumatic fever should be put in first place. As is well known, rheumatic fever morbidity, which decreased during the war years, has subsequently increased. In the Soviet literature a number of works have appeared in which, in addition to a study of the rheumatic psychoses from new theoretical standpoints, the psychopathology is presented in chorea minor and in the nonchoreic forms of rheumatic brain disease (6, 9, 16-20).

Rheumatic psychoses most often occur stormily; however, chronic rheumatic psychoses are also encountered which sometimes pass into a mental deficiency stage.

In the acute phases of rheumatic psychoses the most frequent syndromes are the following: depressive-hypochondriacal, hallucinatory-paranoid, and catatonic. The latter is most often encountered in chorea minor (16, 17).

Disturbances in consciousness are characteristic of the acute stages of rheumatic psychosis. At first, these are dreamlike, oneiroid states which occur in connection with the transition into the sleep; afterwards, the periods of disordered consciousness lengthen, including the daytime hours. Sometimes, elements of delirium are noted. The disturbances mentioned not uncommonly are replaced by stupefaction; sometimes, a catatonic state occurs. Emotional disturbances are typical of rheumatic

psychosis—*anxiety, fear, dejection, and paroxysmal disturbances of sensory synthesis. Hypochondriacal disorders, at the basis of which lie changes in intero-, extero-, and proprioception, are very typical.*

Afterwards, only depressive-hypochondriacal, hallucinatory-paranoid, and catatonic syndromes are manifested distinctly. The psychosis sometimes acquires a considerable similarity to schizophrenia; nevertheless, a number of criteria have been distinguished for the purpose of differential diagnosis (16).

The course of the psychoses is undulant, which is apparently characteristic of allergic conditions. In various cases the psychosis can lead to mental deficiency; however, usually it lasts from several months to a year or more and ends in recovery.

Study of higher nervous activity has made it possible to establish the fact that the toxic-infectious principle produces a protective inhibition in the central nervous system with various phasic states, the clinical expression of which is a whole gamut of disturbances in consciousness—*stupefaction, oneiroid, and delirium states (18, 19, 21).*

In the works of Polish authors—Kolakowska (22, 23), Sinchninska (24), and others, attention is directed both to the psychopathological changes in rheumatic disease and to rheumatic psychoses.

Scheidegger presents data concerning the histopathological examination of the brain in acute rheumatic psychosis which show that rheumatic inflammation of the brain (granuloma of the vessels and intravascular infiltrates) involving chiefly the brain stem underlies it (25). However, similar changes are also observed in the cerebrum.

Facts reported by Bruetsch are of interest (26). The author has found structural changes in schizophrenia specific for rheumatic disease (in agreement with what Beletskiy and Avtsyn (27) and Skobnikova (28) reported in their time).

Much attention has been devoted to the psychic disorders in tuberculous meningitis (29–31). All the authors agree that various types of disorders of consciousness (stupefaction, oneiroid states with striking fantasy experiences, visual illusions, twilight states, and

coma) are typical of the acute phase of tuberculous meningitis. Because of the extensive application of antibiotics, two-thirds of the patients recover; this permits a study of the dynamics of the psychotic states.

Long-lasting but not always gross disorders of consciousness with subsequent prolonged amnesia should be considered characteristic of the course of tuberculous meningitis. In patients who apparently have been fully conscious for a long time, amnesia is noted in connection with the events of this period. In the presence of the memory disorder the intellect as a whole practically does not suffer at all. Pathological changes are particularly pronounced in the brain cisterns.

In the field of children's diseases much attention has recently been given to mumps virus meningitis and to chickenpox encephalitis (32–35). In the former, very severe headaches, a marked degree of clouding of consciousness, sleepiness, and an impairment of sensory synthesis are noted. In chickenpox encephalitis not uncommonly a picture of a severe comatose state occurs with convulsive attacks. On the basis of his own observations, Nilsly asserts that in chickenpox encephalitis a toxic-allergic reaction of the vascular wall occurs with secondary cerebral involvement (36).

In recent years, the psychopathology of measles (including acute psychotic states) has been worked out in detail, and psychopathological disorders typical of various phases of the course have been established (37). Abroad, this problem has been studied by Solomon, Makman, and West (38), but without any attempts at distinguishing the features typical of this infection.

The problem of dysenteric and scarlatinal psychoses is being worked out (39).

In the acute stage of the disease it is hard to draw a line between the toxic-infectious psychoses, where the psychosis occurs on a background of intoxication, and the psychoses which develop on the soil of encephalitis primarily or secondarily affecting the central nervous system.

The neurological symptomatology is the most reliable criterion, but it can also be transitory and does not always serve as a true sign of organic involvement of the brain. It should be

kept in mind, as I. P. Pavlov often emphasized, that there is a possibility of transition of functional into organic, and it is difficult to set a boundary line between them.

In the solving of the problems of infectious psychoses by Soviet psychiatry, pathophysiological methods of investigation are being used on a progressively broader scale with the application of the motor method and speech reinforcement in the A. G. Ivanov-Smolenskiy method, the salivation method, chronaximetry, and electroencephalography (21, 40, 41). The comprehensive study of mental disorders in infections is being conducted in a progressively more complete fashion (for example, the comprehensive study of children with a neurovirus infection occurring with sensory disorders). The reactivity of the body is being studied widely. All this is making it possible to investigate more thoroughly the pathogenetic mechanisms in the infectious psychoses and the defensive properties of the organism.

The treatment of the infectious psychoses is various. In those cases where the character of the infection is known, casual therapy is prescribed; recently, various antibiotic combinations are being used more and more extensively. In the acute stage of the psychosis, along with the fight against dehydration of the body and regular diet, antihistamines and suprarenal and sex hormones are being used. According to the data in the literature, cortisone has proved to be particularly effective in intensifying the adaptive mechanisms of the organism (9). Electric shock, cardiazol shock, insulin coma widely used abroad for the treatment of acute infectious psychoses cannot be convincingly grounded theoretically.

Further study of the infectious psychoses should proceed along the lines of establishing the typical features introduced by various infections into the clinical picture of the psychosis (careful study of the pathomorphological changes proper to infectious psychoses of different etiologies is also needed) and along the lines of perfecting the pathophysiological, biochemical, and immunological methods of study which will permit us to become more familiar with the pathogenetic mechanisms of infectious psychoses and to elaborate rational methods of therapy on this basis.

Preliminary Report of Human Staphylococcal Infection Associated With Mastitis in Dairy Cattle

GORDON D. WALLACE, D.V.M.
WALTER B. QUISENBERRY, M.D., M.P.H.
MAURICE A. DE HARNE, M.D.

THE emergence of strains of antibiotic-resistant staphylococci producing epidemics and endemics of suppurative disease in hospital patients and hospital personnel and spreading from them into the community prompted the Public Health Service and the National Research Council to sponsor the first National Conference on Hospital-Acquired Staphylococcal Disease, held in Atlanta, Ga., September 15-17, 1958. At this meeting Dr. Leroy E. Burney, Surgeon General of the Public Health Service, and others emphasized the hazard of antibiotic-resistant epidemic strains spreading to the community (1).

Staphylococci a Frequent Cause of Mastitis

Staphylococci have long been recognized as important in the etiology of mastitis in dairy cattle. Investigations have also revealed that these organisms are frequent inhabitants of apparently normal bovine mammary glands (2). Improper use of milking machines and other poor husbandry practices can cause trauma to glandular tissue, development of infection, and

Dr. Wallace is serving as consultant in comparative medicine and veterinary public health, Hawaii State Department of Health, Honolulu, on assignment from the Communicable Disease Center of the Public Health Service. Dr. Quisenberry is director of the department's division of preventive medicine, and Dr. De Harne is in private practice at Wahiawa, Oahu.

spread of pathogenic organisms through the herd (3, 4). A wide variety of antibiotics are frequently and often indiscriminately used by dairymen to treat animals suffering from mastitis. This creates an environment suitable to the development of pathogenic staphylococci resistant to antibiotics and an opportunity for cross-infection in the herd.

Recognizing this problem, the division of animal husbandry of the Hawaii Board of Agriculture and Forestry and the division of sanitation and bureau of laboratories of the Hawaii Department of Health conducted a limited survey to determine what bacteriophage types of coagulase-positive staphylococci are present in the milk of some dairy cattle on Oahu. During this survey, epidemic strain phage type 80/81 was found in the milk from four dairy cows—three in one herd.

The following report, believed to be the first of its kind to appear in the literature, describes investigations that associate human infection with mastitis caused by type 80/81 in dairy cattle.

Cows and Humans Found Infected

Upon finding that mastitic mammary secretions from at least three cows in one dairy herd contained staphylococcus phage type 80/81, it was deemed advisable to separate these animals from the commercial herd and culture additional milk samples from them as well as other animals in the herd showing evidence of mastitis. The dairy employees were also given bacteriological examinations.

Nasal cultures were performed on 11 employees working directly with the cattle. These workers were questioned about current and past disease indicative of staphylococcal infection. Six of these men were found to have paronychia on one or more fingers. This was attributed to frequent contact with disinfectant solution (chlorhexidine diacetate) necessary during milking. Specimens for culturing were also taken from the finger lesions. Only one employee gave a history of a frequent occurrence of furuncles or other diseases that could be attributed to staphylococcal infection. This employee had a large draining furuncle on his back

at the waistline, approximately 3 inches lateral to the spinal column. Exudate was collected from this lesion the same day that nasal culturing was performed. In addition, samples of disinfectant solutions used in the milking parlor and swabs from hose nozzles frequently handled by the employees were taken for bacteriological examination.

Nasal cultures from four employees yielded coagulase-positive *Staphylococcus aureus*, with one strain identified as phage type 80/81. This strain was from the anterior nares of the employee whose furuncle exudate also yielded type 80/81. Staphylococci were not isolated from any of the other specimens.

The antibiogram of these human 80/81 strains—resistant to chlortetracycline, oxytetracycline, tetracycline, and dihydrostreptomycin but susceptible to penicillin, chloramphenicol, oleandomycin, bacitracin, neomycin, carbomycin, and novobiocin—was identical to all of the bovine 80/81 strains isolated except that the bovine strains had some resistance to penicillin.

Infection in the Dairyman's Family

Further questioning of the employee found to have type 80/81 infection revealed that he had frequently experienced boils and sore throat during the previous 9 months, starting 3 months after his initial employment by the dairy. He further stated that his wife was currently afflicted with a boil and that his only child, an 18-month-old boy, had been experiencing a chronic sore throat for approximately 3 months and had only recently responded to medical therapy. (It was subsequently learned that the boy had responded to oleandomycin.)

The entire family was advised to seek medical care, and they elected to go to one physician. The father was given a course of TAO (tri-acetyloleandomycin), 1 gm. per day for 4 days. Cultures of nose and throat specimens taken shortly thereafter were negative for staphylococci, and there was no clinical evidence of new furuncle formation. Two weeks later the patient was given a course of chloramphenicol (same dosage schedule as TAO) which was again followed by negative nose and throat cultures. The second course of antibiotics was

thought to be advisable as a prophylactic measure since it was learned that the other members of the patient's family were also infected.

S. aureus phage type 80/81 was isolated from a furuncle on the right labium majus of the wife but not from nose or throat cultures. Subsequent cultures of nose and throat specimens following a course of chloromycetin were also negative, and her furuncle had healed.

Staphylococcus type 80/81 was isolated from the throat but not from the nose of the child. The antibiogram of this isolate was identical to those of the strains obtained from the mother and father. Another nose and throat specimen taken from the child 1 week after 2.5 gms. of chloromycetin had been administered yielded no staphylococci. Additional culturing of the dairy employee and his family is being planned.

Subsequently, two other employees were found to have experienced boils, but, unfortunately, they were discovered too late to obtain exudate for culturing. Additional nasal cultures from both of these men gave negative results.

Cultures of Milk Samples

One of the three cows originally found to be shedding staphylococcus type 80/81 in her milk was sent to slaughter before additional milk samples could be obtained. An additional milk sample from each of the other two animals yielded type 80/81. One of these animals was slaughtered because of low productivity attributed to severe mastitis. The remaining infected animal was treated with intramammary infusions of neomycin under the direction of a veterinarian. After two such treatments, staphylococcus type 80/81 was not detected in milk samples taken from all four quarters, but in 10 days this animal was again found to be excreting staphylococci type 80/81 from one quarter. There was no clinical evidence of mastitis at this time and the milk appeared normal, but the animal was slaughtered because of greatly decreased milk secretion. Pathological and bacteriological examinations of the mammary gland are being performed.

Although it would have been highly desirable, it was not feasible to culture milk samples from every lactating cow in the herd because of the

comparatively large number of animals and the lack of laboratory facilities and personnel. Milk specimens collected from 100 cows or about 10 percent of the herd did not yield staphylococcus type 80/81.

Twenty-one bulk raw milk specimens were collected at different times from the holding vats at the dairy. Milk is cooled and stored in large tanks prior to shipment by tank trucks to the processing plants for pasteurization. Coagulase-positive *S. aureus* was isolated from 17 of these specimens, 13 of which were phage-typable. Two of the typable strains, isolated on separate occasions from the same vat, were identified as the antibiotic-resistant type 80/81 with antibiograms identical to the bovine 80/81 strains originally found. Type 6/42E/47/42B/42D/44A was found in five milk samples, and 42D in three samples. The three remaining isolations were of different types. The types other than 80/81 found in milk are not common to those found in man in Hawaii, and all were susceptible to the antibiotics tested, according to a personal communication from M. Levine and R. H. Tanimoto, bureau of laboratories, Hawaii State Health Department. The finding of phage type 80/81 in the bulk milk samples may indicate that animals not previously detected are shedding this organism or that one of the employees not known to be harboring 80/81 contaminated the milk. Investigations are currently being conducted to detect this source.

Source of Infection Unknown

The available information allows only speculation as to the original source of staphylococcus type 80/81 infection in the dairy herd studied. Coagulase-positive staphylococci have been found commonly in mastitic secretions of a large number of cows in the dairy herd under investigation. Although adequate records are not kept on individual animals by the dairy management, it was learned that prior to the discovery of type 80/81 staphylococci at the dairy, a wide variety of antibiotics had been used by intramammary infusion for the treatment of cows with mastitis. It is possible that the resistant strains developed in bovine mammary glands and are unrelated to the strains of

staphylococci isolated from the dairyman and his family. It is also possible that the human staphylococcal infection was contracted from the cows. The infected employee spent most of his working hours in the hospital barn where cows, including the ones found to be secreting type 80/81 staphylococci, were housed for treatment of mastitis and other ailments.

The third possibility is that the dairyman, or one of his family, contracted type 80/81 infection from an outside source and infected the cows. Except during the birth of his child 18 months previously, none of the family had a history of recent hospitalization. The hospital where the child was born, 9 months before symptoms of staphylococcal disease were evident in the father or mother (and 14 months in the child), has not been known to have a staphylococcal disease problem. Nevertheless, the child or his mother may have acquired the organisms in the hospital and remained asymptomatic carriers, or the family infection could easily have been acquired outside the hospital.

Phage type 80/81 has been the most common type associated with staphylococcal infection in humans in Hawaii. During 1958, phage type 80/81 accounted for 30 percent of coagulase-positive strains identified by the laboratory of the Hawaii State Department of Health. The next most frequent type found accounted for only 5.5 percent (M. Levine and R. H. Tanimoto, personal communication). Similar findings have been reported from other areas (5). Data on phage types found in cattle in Hawaii are limited to a relatively small number of herds and samples.

Increased Virulence and Communicability

Varying opinions appear in the literature concerning the communicability and virulence of staphylococcus type 80/81 as compared with other staphylococci. Blair states (5): "There appears to be little question that staphylococcus of type 80/81 probably possess enhanced virulence and a high degree of communicability . . . and is capable of producing a variety of clinical forms of staphylococcal disease." Wentworth and associates describe family infections persisting for as long as 4 years and requiring extensive medical care and hospitaliza-

tion. The cost to one family for antibiotics and medical care, exclusive of hospitalization, was estimated in excess of \$1,500 (6). Spink presents evidence that infections with antibiotic-resistant strains present more difficult therapeutic problems and appear to be causing a higher case fatality rate than infections with sensitive strains (7). Anderson (8) and Dowling (9) in separate reports recognized the seriousness of the antibiotic-resistant strains but pointed out the need for more information and better methods of determining invasiveness, pathogenicity, and virulence of individual strains.

The virulence and communicability of staphylococcus type 80/81 for dairy cattle and other domestic animals are not yet known, but it should be considered a dangerous organism with potential for causing serious disease in animals and subsequent economic loss to animal industry.

There are definite public health implications in finding staphylococci in dairy cattle similar to the human epidemic strains. Undetected infected animals may present an occupational health hazard and act as foci of infection for rural communities. The ability of Hawaiian strains to produce heat-stable enterotoxins has not been investigated, but this possibility reaffirms the necessity for strict enforcement of refrigeration requirements for raw bulk milk and enforcement of presently accepted time and temperature combinations used in pasteurizing milk.

Summary

Three cows in one dairy herd were found to have mammary glands infected with the antibiotic-resistant staphylococcus phage type 80/81.

Subsequent investigations revealed one dairy

employee and his family to be suffering from staphylococcal disease caused by the same type. This organism was also found in 2 of 21 raw bulk milk samples collected at the dairy.

Treatment of the human cases is described as well as the therapeutic failure in preventing the excretion of type 80/81 in the milk of one dairy cow.

An Alabama study explores the attitudes of patients or their families toward a community mental hygiene program and evaluates the program's effectiveness in relationship to the source of referral.

Patients' Reactions to a Program in Public Mental Health

CARL A. F. HOLLER, M.D., MARTHA B. MUNDY, R.N., M.P.H., ROBERT G. HATTWICK, Ph.D.,
and JEANNE P. NOOJIN

A MENTAL HYGIENE DIVISION was added to the public health program of the Etowah County (Ala.) Health Department on February 1, 1957. The clinic provides psycho-diagnostic and psychotherapeutic services to residents of Etowah County and surrounding counties, on a non-fee basis.

This study was initiated because the staff felt that an evaluation was needed for the purposes of determining whether the services were meeting community needs. The period covered was from February 1, 1957, to November 1, 1958.

A search of the literature shows a singular lack of studies of the evaluation of a public health service by the patients and their families.

The Problem

The policy of the Etowah County Health Department is to make its personnel responsible for the mental health of the county as well as for the physical health. The ultimate goal is

to obtain an integration, on an optimum level, of both mental health and physical health services. In addition to the mental hygiene personnel, other health department workers can be utilized as a community resource for teaching, demonstration, and consultation in the area of prevention of mental illness and promotion of mental health. Because the local need cannot be satisfied by the limited personnel available for the clinic, clinical services have been, and will continue to be, principally diagnostic and recommendatory. This practice will necessitate followup by referral sources and other agencies. Therefore, this study was initiated in order to determine how patients of the clinic and their families accepted and evaluated clinic services and recommendations.

The data incorporated into this report are purely their subjective evaluation; no attempt is made to analyze the validity of their responses. This study has been helpful in identifying some of the areas in our mental hygiene program which, according to the reports of patients and their families, need improvement. Because of their reactions, possible changes in existing policies and practices are under consideration. Another benefit of this study is that the attitudes of those making use of mental hygiene services are made apparent. It is our

Dr. Holler serves as county health officer in the Etowah County Health Department, Gadsden, Ala., in which Miss Mundy is mental health nurse, Dr. Hattwick, clinical psychologist, and Mrs. Noojin, health coordinator.

belief that the effectiveness of such a program is dependent upon the acceptance of it by the local community.

The Etowah County Health Department is in northeast Alabama. The county ranks fourth in population for the State. The total population is 99,390, of which 85 percent are white. In addition, 36 percent of the referrals of the mental hygiene clinic are made by six surrounding counties which have a total population of 240,890 (1). Other services given by the health department are tuberculosis care, sight conservation, dental care, immunizations, statistical reporting, vector control, milk and food inspection, sanitation, bedside nursing, maternal and child health supervision, school health supervision, and control of venereal and other communicable diseases. The health department also conducts inservice education programs for public health nurses and sanitarians from surrounding counties.

Procedure

This study is descriptive in nature and no attempt has been made to analyze critically the responses of patients and their families. It is an attempt to identify certain areas of acceptance and rejection of clinical services given by the mental hygiene division. The term "evaluation" as used in this study is the first of three levels defined by the U.S. Department of Health, Education, and Welfare, in "Evaluation in Mental Health" as: "An estimate which an individual or group places on an activity or service, what it means to the recipients according to their own value system. It should be added that this value system is not necessarily the same as that used by the State, Federal Government, or the scientist, in establishing a service" (2).

Initial plans for this study were made in June 1958. In a staff meeting the psychiatric social worker discussed with the public health nurses the possibility of a survey. It was decided that a questionnaire would be devised, and each of the participants submitted a list of questions which he felt would be pertinent. After careful consideration the group accepted 25 questions to be incorporated into the questionnaire. This preliminary form was sub-

mitted to the health officer for his recommendations and approval. As no funds were available, the possibility of hiring outside interviewers to accumulate the data was eliminated.

It was decided that the public health nurses would be the most effective group for use as interviewers. The group was aware that bias might be introduced, as public health nursing and the mental hygiene service represented the same official agency. Each nurse was encouraged to express her feeling and was given support and instruction in methods of collecting the data with a minimum of bias. The questions contained in the questionnaire were discussed in detail so that all the interviewers would interpret them on the same basis.

A pre-test of the questionnaire was made in mid-October, 1958, on 10 former patients of the clinic or their families. The questionnaire was then revised and reduced to 15 factual, open end, and multiple-choice questions.

On November 1, 1958, all individuals who had been admitted to the mental hygiene service from Etowah County, Ala., and whose case folders had been closed were listed. As nursing time available for this study was limited, the public health nurses were instructed to make only one visit to the home in an effort to interview the patient (if an adult) or the family. Of the 247 cases on file, 121 were interviewed. This number represented 49 percent of the total number of patients admitted to service. Of the total cases on file, 78 percent were children and 22 percent were adults. Of the 121 cases interviewed, 83 percent concerned children and the rest, adults. Ninety-three percent of the questionnaires were answered by family members and 7 percent by adult patients. The survey was concluded on December 31, 1958.

The responses made to the questionnaire have not been compared with the case records on file at the health department. The referral sources were not interviewed in this survey. Therefore, no attempt has been made to evaluate the validity of the information gathered from the patients or families.

At the time of this study, health department policy included five sources of referral. These were physicians, public health nurses, depart-

Table 1. Method of referral to mental hygiene services, Etowah County Health Department, Ala., February 1957–November 1958

Referral sources	Number	Percent
Physicians.....	12	10
Ministers.....	2	1
School.....	25	21
Public health nurses.....	26	22
Departments of pensions and security.....	31	25
Others.....	25	21

ments of pensions and security, schools, and ministers. However, it was found that other referrals had been accepted, such as self, mental health association, court, police, and others.

The largest number of referrals from any one source was from the departments of pensions and security, which referred 25 percent of the individuals seen by the mental health service (table 1). Ranking second were public health nurses, who referred 22 percent. Schools and other sources ranked third with 21 percent each.

The fact that physicians referred but 10 percent of the sample placed them in fifth position, and ministers had a negligible 1 percent. What

does this total of 11 percent from professional people (physicians and ministers) indicate. Is there a lack of understanding of the service? We question this conclusion, as two physicians have served as president of the Etowah County Mental Health Association, one as secretary, and there has been a mental health advisory board appointed by the Etowah County Medical Society. Has there been some lack of communication between the advisory board and the medical society as to the services provided by the mental hygiene division?

The 10 percent of referrals made by physicians represents 12 different individuals, which is approximately one referral for every three physicians practicing in Etowah County. However, it should be noted that these physicians, although they are aware of the service, have made limited use of it. As there are no psychiatrists or psychologists in private practice in this county, are patients being referred to the nearest community with such services, which is 65 miles distant, or is no service of this type being recommended? As 68 percent of the total referrals came from official agencies, does this indicate that tax-supported agencies tend to refer individuals to other tax-supported

agencies more readily than do other sources of referral?

Table 2 indicates that 67 percent of the 121 respondents reported receiving a report and an interpretation. This service was given either by the mental hygiene personnel, the referral source, or by a related agency according to the patients or family. Physicians ranked highest in this respect with 92 percent of the individuals stating that they had received a report. Public health nurses ranked second, followed by schools, departments of pensions and security, ministers, and others. An overall average for all referral sources was 67 percent who acknowledged having received reports.

What is the significance of the 33 percent for those stating that they did not receive a report from the division of mental hygiene or the referral source? What does this mean to us as a service agency in terms of effectiveness of service and public relations? Why did these patients or their families feel that no report was given? How do they interpret the term "report"? Is it possible to develop a method of communication with them that is meaningful? Is it of value to see these individuals if their comprehension of the recommendations is limited or nonexistent?

Answers to the question, "Did you understand the recommendations?" indicate that almost half of the patients or their families did

not fully understand or had no understanding of the recommendations (table 2). Does this lack of understanding result from the use of technical terminology, from lack of time spent with the families, or from lack of ability to meaningfully communicate the interpretation of the results? Is the service of benefit if the recommendations are not clear to the individuals involved?

Can the 31 percent representing those who were able to follow the recommendations in table 2 be interpreted to mean that this percentage of the sample was served adequately? Are recommendations offered beyond the comprehension of these individuals' intellectual, financial, environmental, and emotional levels? According to the sources of referral in table 2, physicians ranked first in imparting information in such a manner that the recommendations could be understood and followed. Schools ranked second, public health nurses third, departments of pensions and security fourth, and others fifth. The ministerial sample of two persons was too small to offer reliable information. Do the foregoing results indicate a need for specific referral sources who are aware of the type of services given by the clinic and who have the professional background necessary to interpret the recommendations to the patient and his family? Does this conclusion suggest that a study should be made as to the

validity of the referrals made to the clinic concerning the needs of the patients for the type of services given?

Evaluation of the ability of the patient and his family or both to understand the report is based on the professional status of the individual making the interpretation (table 3). Results are based on the 83 respondents who stated that they had received a report. This number represents 69 percent of the total sample of 121. From the results, it would appear that the psychiatric social worker was the most effective interpreter. Of those receiving reports, 67 percent felt that they understood the reports; 24 percent had partial comprehension; thus a total of 91 percent of the sample had some comprehension of the recommendations involved.

Of those receiving reports, table 3 shows that 49 percent were able to follow the recommendations and 15 percent were able to follow them partially. This number actually represents 40 percent of the total sample of 121 who could follow the recommendations and 11 percent who could partially follow them. Did the remaining 49 percent receive any benefit from services of the clinic? Despite the lack of an objective report of value received from the clinic, do they promote and support the mental health services? Do they feel that the clinic is meeting the community needs and support the expenditure of tax dollars for clinic services?

The fact that 60 percent of the sample visited the mental hygiene clinic only once and that 16 percent made only two visits (table 4) is sug-

gestive that those who report four or more visits show the greatest amount of improvement in the patient's adjustment. This suggests the possibility that the patients and their families or both need repetition of the recommendations and a more intensive workup.

Conclusion

Some insight has been obtained into the conscious acceptance and rejection of the mental hygiene services of the Etowah County Health Department on the part of the patients and their families.

The information suggests a need for a thorough evaluation of clinic policies and techniques. The following areas should be explored: (a) types of referrals that can be adequately serviced by the mental hygiene clinic; (b) limitation of referrals to certain sources which can adequately interpret the results and follow through with the recommendations; (c) clear designation of responsibility for interpretation and followup service in each case; (d) better understanding by referral sources of the mental hygiene services available; and (e) clarification of the responsibilities of both mental hygiene personnel and the referral sources to the patient.

The referral sources thus would be better able to prepare the patients at the time of referral. They would also be able to interpret more effectively the results and to follow the patient after such clinic services have been terminated.

Our objective is the prevention of mental illness within the framework of public health. A purely clinical approach, on a one-to-one basis, does not appear to be feasible. This study points out that, at least in our community, only 31 percent of these individuals seen stated that they profited from the services. The program, as constituted at the present time, does not appear to satisfy the community needs either from a treatment or prevention standpoint. From a purely clinical viewpoint the results suggest the possibility that in many cases the service may have promoted frustration, indifference, and confusion, because of lack of transmission of the information to the patients or their families, or as a result of an inability to communicate the results to them. This suggests a need for intensive community education so that there is a better understanding of mental hygiene concepts among members of the community.

As a result of this study, the Etowah County Health Department is actively endeavoring to devise methods and techniques not only to improve clinic services, but also in the area of extra clinical functioning.

Poliomyelitis Vaccination

ABOUT 5 years have elapsed since the inception of the national poliomyelitis inoculation program with the licensing of Salk vaccine for commercial production in April 1955. During the past 3 years, the Public Health Service has arranged for the annual collection of poliomyelitis vaccination information by means of household sample surveys of the national population. The surveys have provided national estimates of the number of persons by age groups of those who had not had any inoculations and those who had received one, two, and three inoculations.

This monograph presents the statistics derived from the survey conducted in August 1957, the first and most extensive of the national poliomyelitis surveys sponsored by the Public Health Service. The extent of participation of the population, as indicated by the number of inoculations received, is shown by age, family income, sex, marital status, color, geographic region, and type of area. These data have been used extensively for purposes of evaluating and planning the national poliomyelitis vaccination program. They are indispensable to epidemiological studies and studies concerned with the vaccine's effectiveness. They are also sugges-

tive of factors affecting the population's participation in preventive health programs.

The early priorities of the vaccination program were important factors in establishing, by August 1957, substantial differentials in participation between population groups. Participation (the proportion that had received at least one inoculation) was highest for children 1 to 19 years of age, particularly among those 5 to 14. The level of participation was about the same for infants under 1 year and adults in the age group 20 to 40 years. Within the latter group, participation decreased with advancing age. In the age range of highest fertility, there was a substantial difference between male and female participation, reflecting higher participation for women. These results were logical consequences of priorities of the vaccination program which selected persons 5 to 9 years of age as the initial vaccination target group and then gradually extended the priorities to include adjacent age groups and pregnant women. The first poliomyelitis inoculation was rarely administered during the 6-month period after birth, accounting for the low rate of participation in infants.

Public Health Monograph No. 61

Population Characteristics and Participation in the Poliomyelitis Vaccination Program. By Monroe G. Sirken and Berthold Brenner. Public Health Monograph No. 61 (PHS Pub. No. 723), 37 pages. U.S. Government Printing Office, Washington, D.C., 1960. 30 cents.

The accompanying summary covers the principal contents of Public Health Monograph No. 61, published concurrently with this issue of *Public Health Reports*. The authors are with the Actuarial Analysis and Survey Methods Section of the Na-

tional Office of Vital Statistics, Public Health Service.

For readers wishing the data in full, copies are on sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. Official agencies and others directly concerned may obtain single sample copies without charge from the Public Inquiries Branch, Office of Information, Public Health Service. Copies will be found also in the libraries of professional schools and the major universities and in selected public libraries.

Within age groups, participation differentials were noted between geographic regions, areas of residence, and color groups. Generally, the proportion of the population that received at least one inoculation was lower in the South than in other regions, lower outside Standard Metropolitan Areas, and lower among the nonwhite population.

Participation in the inoculation program was strongly associated with family income. Although the pattern of participation by age was essentially the same within four broad income levels, the proportion of the population inoculated one or more times increased with income for virtually all age groups. The association between participation and income held for each region and area of residence. The relationship was much more marked for the white population than for the nonwhite population. In fact, among nonwhite children of school age, participation was not correlated with family income.

Of the 60 million persons vaccinated by August 1957, slightly more than half completed the series of three inoculations. The priorities of the vaccination program were quite evident in the differences between the age groups in the proportion that had completed three inoculations. Children in the age group 5 to 9 years had the highest completed participation rate, and those in the age group 10 to 14 years had nearly as high a completion rate. The rate was appreciably lower for preschool children and for persons 15 years and older, and it declined precipitously with advancing age. For the reproductive age groups, the completed participation rates were higher among women. Generally, completed participation rates were lower

in the South than in other regions, lower outside Standard Metropolitan Areas, lower among the nonwhite population, and lower for lower income families.

The population that had started but not completed the series of three inoculations (persons having received at most one or two inoculations) represented the current or more recent participants in the sense that they had received their first inoculation during a period that rarely extended more than a few months prior to the survey date. It is noteworthy that there was less disparity between adults and children in the proportion who had completed one or two inoculations than there was in the proportion that had completed three inoculations. For children under 20 years, the percentage that started but had not completed the series of three inoculations was about the same for preschool, school, and the 15- to 19-year age groups, although it tended to be slightly lower for the school-age group, 5-14 years, which had achieved the highest participation levels. Major differentials by geographic region, area of residence, color, and family income were not evident either. Apparently some major disparities in the levels of participation between the age groups under 20 years were not being increased further during the summer of 1957. At the adult ages, however, the reverse was noted—the disparities by age, sex, and color in the levels of participation appeared to be increasing.

A chronology of the major events and factors affecting the population's participation in the poliomyelitis inoculation program between May 1953 and August 1957 is presented in the appendix.

Editor's Correction

In the article entitled "Relationship of Excess Weight in Children and Adults," by Sidney Abraham and Marie Nordsieck, *Public Health Reports*, March 1960, figure 1, page 268, should be captioned "Adult weight status of overweight children of both sexes, 10 to 13 years of age, Hagerstown, Md., 1937-39." Figure 2, page 269, should be captioned "Adult weight status of average weight children of both sexes, 10 to 13 years of age, Hagerstown, Md., 1937-39."

Federal Publications

Uranium Miners. Your ounce of prevention. *PHS Publication No. 708; 1959; 16 pages; 10 cents.*

This pamphlet alerts uranium miners and operator-owners to certain occupational health hazards inherent in their jobs and informs them of necessary protective measures.

It is illustrated by line drawings and simple, brief descriptions of the hazards of radiation, silicosis, and dangerous gases and conditions are presented together with recommendations for their control.

School Mental Health. *PHS Publication No. 704; 1959; 11 pages; 10 cents.*

Program activities of the National Institute of Mental Health relating to school mental health are briefly described. A few examples of current projects are given for each program area.

A list of agencies designated as State mental health authorities and a list of the regional offices of the Department of Health, Education, and Welfare are included for the convenience of those who wish information on State school mental health programs.

VD Fact Sheet, 1959. Basic statistics on the venereal disease problem in the United States. *PHS Publication No. 341 (16th revision); 1959; 23 pages.*

Latest statistics on venereal disease incidence, prevalence, reported morbidity, mortality, and therapeutic methods are given. Information on trends in health departments' casefinding and epidemiological activities are also given.

Estimated cost of uncontrolled syphilis, current penicillin reaction studies, and other basic material complete the data.

The Child With a Missing Arm or Leg. *Children's Bureau Folder No. 49; 1959; 25 pages; 10 cents.*

Parents of child amputees are given practical information about

helping their children become independent by learning to use prostheses.

The folder emphasizes the importance of the use of prosthetic teams, including doctors, social workers, prosthetists, therapists, and nurses, in helping the child get a correct fitting and in training him to use the device.

Milk Sanitation Administration. Selected lectures. *PHS Publication No. 728; 1960; 208 pages.*

Administrative programs of the Public Health Service as related to State and local procedures for the milk industry are developed in detail. Separate lectures deal with the operational program of the Public Health Service and survey and laboratory certification procedures for interstate and intrastate shipments of milk and milk products.

Included are descriptions of recent research in the inactivation of pathogenic micro-organisms in milk and milk products exposed to 'ultra-high temperatures. Other papers discuss animal diseases, vector control procedures, dairy plant sanitation, and noninfectious milkborne diseases.

Although developed primarily for State and local public health administrators, this syllabus should be useful to universities, the dairy industry, and the Armed Forces.

The Public Health Nurse in Your Community. *PHS Publication No. 47; revised 1959; 16 pages.*

This popularly written booklet tells of the role of the public health nurse as an indispensable member of the public health team in the prevention and control of disease and in the promotion and maintenance of good health at home, at work, and in school.

It was prepared as a reference guide for use in explaining to high school students, university students, and others the challenge of public health nursing.

Heart Disease. *PHS Publication No. 45 (Health Information Series No. 63); revised 1959; leaflet; 5 cents, \$2.75 per 100.* Directed to the general public. Briefly explains coronary artery disease, hypertension, and rheumatic heart disease. Stresses importance of regular physical examinations.

Hypertension. *PHS Publication No. 146 (Health Information Series No. 69); revised 1959; leaflet; 5 cents, \$2.70 per 100.* Describes in lay language what happens in hypertension, its symptoms, and methods of treatment. Discusses role of tension and stresses importance of medical care.

Varicose Veins. *PHS Publication No. 154 (Health Information Series No. 50); revised 1959; leaflet; 5 cents, \$2.25 per 100.* Simply written description of varicose veins, telling what is known about the causes of this disorder and about contemporary methods of treatment.

Leptospirosis. *PHS Publication No. 696 (Health Information Series No. 98); 1959; leaflet; 5 cents, \$2.50 per 100.* Directed to the general public, especially dog owners and others who may come in contact with the disease. Lists the animal carriers, of leptospirae, the methods of spread from animals to humans, and symptoms of the disease in humans. Touches on treatment as well as prevention, stressing sanitation measures.

This section carries announcements of new publications prepared by the Public Health Service and of selected publications prepared with Federal support.

Nutrition for the Later Years of Life

By ANCEL KEYS, Ph.D.

"Nutrition for the later years of life" implies that older people have special nutritional problems simply because they are older. The suggestion is that dietary practices considered good for younger adults may not fit precisely the needs of older people. Actually, there is practically no evidence that age, by itself, produces nutritional problems which do not have their counterparts at all ages in adult life. However, the frequency of certain problems changes with age and there are some general trends which need attention from those who advise or care for elderly persons, as well as from the elderly person himself.

It is impossible to specify any particular age which this discussion applies, or begins to apply. Physiologically, a modern man is

en-
aged.

spe

MAY 1952, pp. 484-489

Nutritional needs of older people are not different in kind from those of any age, Dr. Ancel Keys points out. They only differ in amount; proteins, fats, carbohydrates, vitamins, minerals, and salts all have their place in the diet.

New Horizon in Mass Inoculation

RICHARD L. TOWLE, M.A.

MASS immunization programs are beset with many difficulties, not least of which is the time-consuming operation associated directly with inoculation of the vaccinee. Several years ago, U.S. Army scientists applied the jet injection principle (1) in the development of an automatic multiple-dose syringe (2) for immunizing large groups of people. This instrument, with some improvements, has been employed on a limited scale by the Armed Forces with encouraging results. The time required to vaccinate groups of men was much less when the jet injector was used than when the ordinary syringe and needle method was followed. Moreover, experience indicated that the immunological responses elicited by several types of vaccine administered by jet injection were comparable to those obtained by the usual methods (3-5).

It remained to be determined whether the procedure which seemed practical for large-scale immunization of military personnel might be equally useful for civilian groups. The present report describes the results obtained in mass immunization programs in Pakistan in which cholera and typhoid vaccines were administered to the civilian population by means of a Hypospray Multidose Jet Injector (4). This instrument is compact, fitting into a container the size of an overnight suitcase. Vaccine is forced through a minute aperture under sufficiently high pressure so that the jetstream penetrates the skin and enters the subcutaneous tissue. The vaccine,

in its course from the reservoir bottle to the aperture, remains in a closed, sterile system. Pressure for injection is applied to a plunger by release of powerful springs. Power for cocking the springs is obtained from a hydraulic system activated by an electric motor. The entire process of loading the discharge chamber with vaccine, cocking the drive springs, and inoculating the immunogen into the patient requires only a few seconds.

East Pakistan is one of the few remaining endemic areas of cholera in the world; the Province usually suffers over 15,000 attacks and 10,000 deaths yearly (6). It is probable that, owing to inadequate reporting of infectious diseases, these figures are not entirely reliable.

But it is known that cholera reaches two peaks during the year, the first in May prior to the onset of the summer monsoon rains and the second starting in September at the end of the monsoon and continuing through the months of October, November, and December.

Immunizations in East Pakistan, except during emergencies such as the 1958 smallpox epidemic, are carried on by the limited staff of the Directorate of Health Services. The population of East Pakistan is approximately 46 million people. There are about 400 sanitary inspectors, or about 1 per 100,000, each supervising 2 to 3 health assistants who are responsible, among other duties, for the complete immunization of the people. This means only 1 vaccinator and inoculator for approximately every 40,000 persons.

Immunization teams are handicapped by travel conditions. There are comparatively few roads, rail service is limited, and air service within each Province is almost nonexistent.

Mr. Towle is field sanitarian adviser with the International Cooperation Administration's U.S. Operations Mission to Pakistan, Dacca, East Pakistan.

These limitations, coupled with the fact that most of the land is under water for several months during the monsoon, severely hamper the mobility of the health workers. Within each thana, a political unit of roughly 100,000 population, nearly all local movement is confined to foot or small country boats.

The psychological aspect of the use of the syringe and needle, itself is another obstacle to immunization. In any population of any country, many people actually shrink from not only the sight but the idea of the needle. This is especially true in East Pakistan where so many are comparatively uneducated villagers. In many areas they do not understand the nature of disease or preventive measures. Not understanding, they feel no stimulus to overcome the apprehension against the needle the way people might in other societies. The purdah system among the Moslem peoples further complicates matters by making it extremely difficult to reach the female element of the population.

Even the educated classes have misgivings about immunization because the majority of injections have been given with an unsterilized syringe and needle, with the risk of transmitting malaria, syphilis, or hepatitis, which are common in this part of the world.

Taking these conditions into consideration, the task remained to prove the utility of the machine in different areas and in various situations.

Initially, demonstrations of the machine were given to different groups. This was done to familiarize community leaders with the jet injector and to determine the reaction of the people toward this new method of inoculation. Demonstrations were given to doctors, medical students, civic groups, health workers, the military, students, and various women's groups in Dacca and throughout the Province. In all instances the reaction was highly favorable. The fact that no needle was used seemed to impress the people more than any other factor. Also encouraging were the numerous comments regarding the relative absence of pain and the speed of inoculation.

Although the general response to these numerous demonstrations was completely positive, the majority of these people were of the educated classes. It remained to be seen whether the re-

action would be as favorable among the less educated groups, to which most of the population of East Pakistan belong. These were the people exposed to disease, the ones who would determine the effect of immunization efforts.

During the following months, accompanied by a Pakistani team usually comprising a doctor and two sanitary inspectors, I took the injector into many areas of the Province, inoculating for cholera. We inoculated people in areas easily accessible, in some almost completely inaccessible, and in cities, small towns, and market areas. We tried to select places which would give us a cross section of East Pakistan.

Inoculations in Urban Areas

In mass inoculation in city areas, it is thought that the machine proved itself without doubt. In most instances, inoculations were done from a station wagon equipped with a generator which provided electricity for the injectors and a microphone and speaker for publicity. There was no problem in attracting crowds; a constant line waited for inoculation.

An excellent example of the capability of the machines was shown in Dacca during the October-November mass inoculation program

Hypospray Multidose Jet Injector

against cholera. Thousands were inoculated daily, with two injectors in operation. The highest figure for 1 day totaled 6,759. Sanitary inspectors and doctors, working with syringe and needle during the campaign, were reporting about 100 inoculations per inoculator per day. It was clearly indicated that one injector could do the work of 25 to 30 men.

The only experience of inoculating with the injectors outside of East Pakistan was in the first week of July in Karachi, West Pakistan. Owing to excessive rainfall in June, much of Karachi was flooded. Nearly all of the refugee colony areas were under water, and there arose considerable danger of a typhoid epidemic. Thirty centers were set up throughout the stricken area for inoculation against typhoid fever, paratyphoid fever, and cholera. The injectors were brought from East Pakistan to aid in the fight. In $4\frac{1}{2}$ days, with only one machine operating, approximately 20,000 persons

were inoculated. The entire staff of the 30 centers, inoculating by syringe and needle, were only able to inoculate about the same number during the same period.

As the work in a municipal area is carried on most successfully as an outdoor operation, most of the persons inoculated were men and children. Few women were reached in this situation because of the purdah system and the social restrictions on women moving about in public. To overcome this difficulty, we set up special centers in buildings for women only. Attendance depended greatly on selection of the site, time of inoculation, and adequate publicity.

The experience of inoculating in urban areas was highly encouraging. With adequate planning, there is no doubt that jet injection can be successful in treating most of a population's men, women, and children in a minimum of time, whether in an emergency situation or in routine preventive programs.

The hats, or market areas, of Bengal also provide excellent opportunity to reach the maximum number in the minimum period. These weekly markets attract gatherings ranging from a few hundred to as many as 20,000 people, according to their size, location, and importance. In a central location in the hat, even without publicity, it has been comparatively easy to inoculate 500 persons an hour with one machine.

The larger markets, such as the Ghior Hat located in Manikganj Subdivision, Dacca District, provide an excellent opportunity to reach many of the people who would be otherwise comparatively inaccessible and also at the highest risk. People come 40 or 50 miles to a hat to sell or exchange produce and animals. Many come by river boats, which constitute the major mode of transportation in the delta area. As most of these river people live on their boats and are constantly moving, it is practically impossible to reach them at any other time. The river satisfies practically all their needs for drinking, washing, and cooking water. All of the rivers are congested with these riparian ramblers.

People living on or near the rivers, and their animals, use them for all purposes. Latrines overhanging the banks are a common sight. There is a chronic threat of infection therefore to the people living on or near the waterways.

Even though most of the people at the hats

are men and children, it is felt that, by the inoculation of this great mass of transients, it may be possible to break one of the more important links in the chain of disease, by means of the jet injector, the one instrument by which it is possible to inoculate enough of these persons quickly. The duration of these hats is only 1 day per week. If the people are not reached on that day, they may carry infection throughout the Province.

Inoculations in Rural Areas

While there remains little doubt that the injectors can be used successfully in places, such as municipal areas and markets, where a great number of people congregate, the principal question concerns their utility in rural areas. In East Pakistan approximately 90 percent of the population of 46 million live in villages. It is estimated that of this 90 percent, at least 40 percent are using water supplies that are considered unsafe. These therefore are the population at greatest risk.

With this factor in mind we set up experimental mass inoculation campaigns in rural areas in different places throughout the Province.

Some of these were easily accessible by road, some by river in either launches or country boats, and some only by foot. All proved of value and brought many facts to light which will prove of value in future mass inoculation.

Mass cholera inoculation, Debidwar Union, Debidwar Thana, Tippera District, East Pakistan

Village	Population	Inoculations					Inoculation time (hours)	Approximate travel time (hours)
		Men	Women	Children	Total	Percent		
Bhoshna	520	104	115	159	378	73	2½	1¼
Champanagar	510	82	59	150	291	57	1	1

Total	10,170	2,092	1,157	2,112	5,361	52.7	19½	13

One campaign typical of rural East Pakistan from the standpoint of type of area, concentration of population, and transportation facilities was in Debidwar Thana, Tippera District. This was an area of average-sized villages accessible only by foot. From this thana we selected one union, a political land unit of from 8,000 to 12,000 population, and inoculated on a village-to-village basis throughout the area. The villagers were informed of the expected time of our arrival by the chowkidars, village officials who serve as registrars, night guards, and tax collectors, and the arrangements and selection of sites were left in the hands of the village leaders. The table shows the results of this controlled experiment. As previously stated, this area was typical as to terrain and people, and the results obtained were about the same as in other areas throughout the Province.

Many conclusions are apparent from this table and many more from observation during the inoculation periods. The total time consumed in this operation was approximately 32½ hours, or about four average working days. As only one machine was used in the operation, the average rate of inoculation was 1,340 per day per machine. Inoculators who had previously worked in this area reported the maximum number that could be done by one man with syringe and needle would be 100. So, despite the fact that these figures are small compared with those of urban areas, the injector was still doing the work of 13 men.

Discussion

The data clearly indicate a great variation in the percentages of persons inoculated in different villages, ranging from 27 percent to 95 percent. This could be traced to many different causes. In Chhota Alampur, Bara Alampur, and Shailchar, no previous notice had been given by the chowkidars. Because of this, many of the people were away from the village and working in the fields at the time of our arrival. In Bhinglabari, a village which is spread out over a wide area, it was raining hard during the time of inoculation and the villagers had great difficulty in reaching the site. Thus, in the four villages with the lowest percentages of inoculations, the poor showing could be traced to lack of notification,

which can be remedied, and to weather, an unavoidable factor.

The cooperation and interest of the village leaders was another element which greatly influenced the success of the program in each village. In the combined villages of Kanibil and Biniapara, the leader was an energetic person who so fully believed in the program that he went personally from house to house through both villages before our arrival and urged the people to come forward. His efforts were rewarded by the inoculation of 95 percent of the population of these two villages. The percentage of inoculation in the other villages seemed to vary proportionately with the interest and efforts of the leaders.

This again is a controllable factor. If these leaders can be called together before a program and fully educated as to the need for inoculation, the success of the campaign will be assured. As these leaders are usually older, highly respected persons, the people of their villages in most cases will follow their advice without serious question. Although total education of all the people in this respect would be the ideal, we can still accomplish our purpose by reaching this small influential group.

As the purdah system is more strictly observed in villages than in the cities, we were concerned whether the women would come forward to be inoculated. In view of this, the selection of the site of inoculation in the villages was of primary importance. We tried to select locations where the women would be protected from the eyes of men by a bamboo matting or screen as they approached to be inoculated. We found that, although they would not present themselves where men were gathered, they apparently had no objections to being seen by the person giving the inoculations, accepting him as a professional person. In most of the villages, there was no great difference in the numbers of men and women inoculated.

The one exception to this was in Debidwar, where the site selected by the officials was on the police station grounds in the center of a large open area. There was no way in which the women could approach with protection from the eyes of the many men gathered there.

Consequently few women came forward. This indicated that the site for inoculations must be selected with careful consideration of local customs.

We feel that the experiment was reasonably successful, since 52.7 percent of the population of the entire union were inoculated. We think, however, that the program could have been even more successful. Most of the factors that accounted for the low percentage of persons inoculated are remediable.

The experience at Debidwar is a fairly accurate picture of inoculations in rural areas. Some earlier campaigns were not so successful and a few later ones, through experience, were more successful. In these experimental mass inoculations extending over a period of 9 months, we have learned how to organize a program for the effective use of the jet injector in all sorts of difficult situations. We feel strongly, therefore, that these machines can be used effectively not only in fighting cholera here in East Pakistan but in the prevention of disease in any situation which calls for mass inoculation.

The utility of the injectors having been established, classes have recently been started training sanitary inspectors and doctors, not only in the operation of the machines but also in the complete repair and maintenance of them. It cannot be overemphasized that because of the intricate nature of the injector and inevitable breakdowns during field operations, the operator should not only be a competent inoculator but also a skilled technician.

Plans are presently underway to supply injectors in sufficient numbers to enable the men who are being trained to take over the major burden of mass inoculation in East Pakistan. When these plans have been realized, we will find a new horizon in the field of mass inoculation which may in time aid in the elimination of epidemics.

Hospitalization Experience of the Indigent in New Jersey

SAM SHAPIRO and VIRGINIA V. VAHEY

IN 1958, the New Jersey State Legislature authorized the establishment of a temporary commission to study and make recommendations on the administration of public medical care in the State. This action became necessary because of the problems that had arisen from the diversity and complexity of the many methods and agencies being used to provide medical care for public assistance recipients and other persons unable to meet the cost of medical care out of their own income and resources.

The financing of hospital care for these persons presents the most difficulties. Hospitals receive public funds in New Jersey for the care of public assistance patients and the medically indigent primarily through lump-sum appropriations of the many municipal or county governments. Under this system, payment is often not based on the amount of care given or on the per diem cost of providing care. As a result, the greatest problem the voluntary hospitals in New Jersey face, according to the representatives of the New Jersey Hospital Association, is the strain on the hospital's financial stability caused by care provided the indigent.

The alternative to the present complex system of appropriations and expenditures viewed favorably (and subsequently recommended) by the New Jersey Commission to Study the

Administration of Public Medical Care was the payment of hospitals "on a per diem basis, the costs of which are determined on the basis of a sound reimbursable cost formula." An essential element in considering costs under this type of payment was the hospitalization experience of the public assistance recipients and the medically indigent in the various counties of the State. A full picture of this experience, however, could not be obtained from existing records or reports. Admission records in many hospitals do not identify the individual's public assistance status or indicate whether he is medically indigent. In view of this situation, the commission, in cooperation with the New Jersey Hospital Association, conducted a survey to obtain the basic data needed to project costs (1).

General Hospitals in New Jersey

There are 152 hospitals in the State covering a wide range of functions and under varied types of governmental and nongovernmental control. The commission's interest was confined to the 86 short-stay general and maternity hospitals in the State; 82 are voluntary hospitals operated on a nonprofit basis, and the remaining 4 are city or county hospitals. In addition, there are nursing homes which take care of their residents' illnesses, specialty hospitals, Federal institutions, such as veterans hospitals, State hospitals, and public medical institutions which include medical sections of county or city infirmaries operated for chronically ill persons whose stay generally extends over long periods of time.

In 1958, there were about 610,000 admissions

Mr. Shapiro, director of the division of research and statistics, Health Insurance Plan of Greater New York, served as hospital study consultant, and Miss Vahey was project director for the New Jersey Commission to Study the Administration of Public Medical Care. Miss Vahey is now medical care administration specialist with the Division of Public Health Methods, Public Health Service.

to short-term hospitals in New Jersey. This represented an admission rate of 106 per 1,000 population in the State, lower than the national average of 125 per 1,000 persons (2). (New Jersey's rate may be comparatively low because some State residents enter hospitals in neighboring New York and Pennsylvania.) From the study, it appears that almost seven out of eight of the admissions are semiprivate and private; the rest are general service ward admissions. In many hospitals semiprivate and general service ward patients have similar facilities; the only difference between them is that the former have private physicians, and the latter receive free medical care from staff physicians while in the hospital.

Scope of Survey

In the survey special forms were mailed to short-term general hospitals in New Jersey with the request that a form be filled out for each person admitted as a general service ward case (a patient who did not have a private physician in attendance) during the 5-week period March 15–April 18, 1959. The pay status of the patient at time of admission was called for on the form for the purpose of distinguishing the following three categories of patients:

- Those paying in whole or in part for their bed care, either through hospital insurance or their own resources.
- Those receiving public assistance and the specific type of assistance program.
- Those considered medically indigent by the hospital and not in receipt of public assistance.

No attempt was made to define "medical indigency" since criteria for medical indigency were still to be established. A special inquiry to the hospitals revealed that the definition of medical indigency varied greatly from one hospital to another. A number of the hospitals base their decisions on detailed financial statements, others on the recommendation of the physician. Accordingly, statistics on the "medically indigent" developed through this survey refer to this category of patients as the hospitals defined it administratively early in 1959.

Also recorded on the survey form at time of admission were the patient's age, sex, and the

municipality where he was living. Later all forms were returned to the hospitals for dates of discharge and any change in pay status of the patient. It was anticipated that an appreciable number of the patients who were admitted as general service ward cases with the expectation of payment being made by them or by hospital insurance would become "free patients" before their discharge from the hospital. This did occur, but in the overwhelming majority of the cases their free pay status was retroactive to the date of admission.

Patients admitted as semiprivate or private cases and subsequently transferred to a general service ward were omitted from the survey. A telephone inquiry to six widely scattered hospitals showed that there were extremely few such patients and their exclusion would have little effect on any estimates of hospital usage by the medically indigent.

Sixty-two of the 86 short-stay hospitals in the State provided data for the study period. Four other hospitals stated they had no general service ward cases. The remaining 20 accounted for an estimated 5–6 percent of the total general service ward admissions in the State in 1958. No adjustments have been made for this percentage in the statistical results of the survey.

Results of the Survey

Hospital Admissions and Rates

The 5-week study conducted by the commission indicated that, during the course of the year, there are about 79,500 admissions of general service ward patients in New Jersey. Payment is made by Blue Cross and other insurance companies for 11,000, or 14 percent, of all general service ward cases. Another 27 percent are patients who pay all or part of their hospital bed care through their own resources or for whom payment is made by relatives. The remainder fall into one of two general categories, public assistance cases or medically indigent. The balance of this report is concerned with these two groups.

Based on the information obtained from the general hospitals, it is estimated that there are approximately 12,640 admissions of persons on public assistance in a year (table 1). About

Table 1. Annual numbers, rates, and duration of stay of general service ward admissions in New Jersey hospitals, public assistance recipients and the medically indigent

Pay status on admission	Number of admissions	Admissions per 1,000 persons receiving assistance	Average duration of stay (days)	Total days in hospital	Days per person receiving assistance
Public assistance.....	12,640	122	11.7	148,460	1.4
Categorical assistance.....	5,600	92	12.4	69,240	1.1

Aid to dependent children.....	2,530	73	6.8	17,110	.5
Aid to blind.....	60	(²)	(²)	580	(²)
General assistance.....	7,040	164	11.3	79,220	1.8
Crippled children and rehabilitation.....	340	(³)	16.8	5,710	(³)
Medically indigent.....	32,080	-----	11.0	352,490	-----

¹ Exclusion of persons on OAA rolls who are in nursing homes and public medical institutions from the total number of OAA recipients raises the hospitalization rate to 142 per 1,000.

² Not computed, too few cases in 5 weeks' sample.

³ Enrollment data for crippled children program not available for computation of rates.

NOTE: Annual figures in all tables based on 5-week survey (Mar. 15-Apr. 18, 1959) of admissions to short-term general hospitals in New Jersey.

half of these patients come from the general assistance rolls, and all but a small proportion of the others are on old-age assistance or aid to dependent children. This situation reflects, of course, the fact that the three programs, General Assistance, OAA, and ADC, account for over 95 percent of all the persons receiving some form of public assistance.

When placed on a rate basis, the general assistance and disability assistance programs have the highest hospitalization rates (164 and 129 per 1,000 recipients, respectively). The relatively high rate for persons on disability assistance is understandable in view of the nature of the program, while the comparatively high figure for general assistance is undoubtedly a reflection of the fact that ill health and indigency are often interrelated.

The lowest rate in the public assistance program in New Jersey is found among persons receiving ADC. In part, this is attributable to the special age composition of the group; that is, it is heavily weighted with children. (Because of the small number of cases, rates for aid to blind could not be calculated.)

Contrary to what may have been expected, the rate for OAA is not very high. This, however, requires some explanation. A large proportion (18 percent) of those on OAA rolls are in nursing homes and public medical institutions and are not available for admission to

general hospitals in the usual way. Exclusion of these persons from the number of OAA recipients increases the rate from 117 to 142 per 1,000, which is close to the highest, the rate for general assistance.

Important as the number of public assistance cases are to the hospitals in providing general service ward care, the medically indigent represent a far more significant group. The 5-week survey showed that in New Jersey, the volume of admissions of medically indigent is two to three times that of persons on the public assistance rolls. On an annual basis, there are an estimated 32,080 admissions of medically indigent persons as compared with 12,640 for all public assistance programs combined.

A sizable segment of the hospitalizations of the medically indigent and those on public assistance is accounted for by the aged. About a fourth of the admissions in the latter group involve persons 65 years of age or older (table 2). In view of the inclusion of OAA in this category, this high a proportion is understandable. With regard to the medically indigent, the proportion is not much less. The aged account for almost a fifth of the hospitalizations, although only 10 percent of the total population in the State are 65 or older. The discrepancy is due to some extent, of course, to higher hospitalization rates among the aged

Table 2. Percent of general service ward care in New Jersey hospitals accounted for by persons 65 years or older, public assistance recipients and the medically indigent

Pay status on admission	Percent of admissions accounted for by those 65 or older	Percent of days accounted for by those 65 or older
Public assistance.....	22.8	34.3
Categorical assistance..	38.1	58.2
General assistance.....	8.7	13.5
Medically indigent.....	19.3	28.7

¹ Virtually all of the aged are OAA recipients.

NOTE: Data for the country as a whole show that 10.4 percent of all patients discharged from short-term general hospitals were 65 years of age or older; these patients accounted for 18.0 percent of all hospital days. Part of the difference between these figures and New Jersey's is due to the exclusion from national data of hospital care for persons who died during the year.

SOURCE: U.S. Public Health Service: Health statistics from the U.S. National Health Survey. Hospitalization: patients discharged from short-stay hospitals, United States, July 1957-June 1958. PHS Pub. No. 584-B7. Washington, D.C., U.S. Government Printing Office, 1958, 40 pages.

than in the population generally. Another important factor is unquestionably the existence of lower incomes among the aged combined with less extensive coverage by Blue Cross and other types of health insurance in this group.

Days in Hospital

In addition to volume of admissions and rates per 1,000 persons receiving aid, another element that must be considered is the duration of stay per hospitalization. Table 1 shows that the average length of stay is high in all groups, including the medically indigent, except ADC. In the general population in New Jersey, the average is far lower, about 8.2 days per admission to short-term general and other special hospitals (2). The reasons for the difference are not clear, but age differentials alone probably do not explain it. More significant may be the greater prevalence of serious illnesses among the indigent and possibly a pattern of use of hospitals that results in more long-term stays.

This conjecture is supported by the data in table 3 which gives the proportion of patients that stay in the hospital for specified periods of time. While the figures may not appear un-

usually high for the aged (OAA recipients), the fact that large percentages of general assistance and medically indigent patients were in the hospital for 25 or more days, for example, suggests that an intensive study of the length of stay in hospitals of indigent patients would be profitable.

The most important single measure of hospital utilization for estimating costs of a program is the aggregate number of days in the hospital. It is clear that when approached from this standpoint, many of the relationships previously taken up are not changed appreciably (table 1). The medically indigent account for considerably more hospital days than persons on all public assistance rolls combined. Projections of the 5 weeks' study data to a full year's experience indicate that the medically indigent in New Jersey spend about 352,490 days in the hospital during the year as general service ward cases. The corresponding figure for those on public assistance is only about two-fifths as large (148,460).

Local Area Data

The number of days spent in the hospital during the year by the medically indigent and those on public assistance varied enormously

Table 3. Percent of general service ward patients in New Jersey hospitals for specified periods of time, public assistance recipients and the medically indigent

Pay status on admission	Percent of patients whose hospital stay is at least—			
	8 days	15 days	25 days	35 days
Public assistance ¹	42.9	23.1	11.9	6.2
Categorical assistance ¹ ..	37.8	21.9	13.3	8.0
Old age assistance.....	65.6	42.3	27.9	16.7
Disability assistance....	47.3	28.4	16.2	9.5
Aid to dependent children.....	25.3	11.1	4.9	3.3
General assistance.....	47.7	24.2	10.6	4.6
Medically indigent.....	40.4	21.3	11.3	6.8

¹ Includes aid to blind not shown separately.

NOTE: Data for the country as a whole indicate that 29.4 percent of the patients discharged from short-term general hospitals stayed at least 8 days; 11.4 percent stayed at least 15 days; and 3.5 percent stayed at least 31 days.

SOURCE: See table 2.

Table 4. Annual number of days, general service ward admissions in New Jersey hospitals, by size of community, public assistance recipients and the medically indigent

Pay status on admission	Total State	Communities with population of—			
		Less than 10,000	10,000– 50,000	50,000– 100,000	100,000 or more
	Number of hospital days per 1,000 population per year

	Estimated number of hospital days per year				
Public assistance.....	1 148,090	19,590	34,570	24,990	68,940
Categorical assistance.....	69,240	11,770	15,020	6,700	35,750
General assistance.....	1 78,850	7,820	19,550	18,290	33,190
Medically indigent.....	1 350,830	27,340	61,720	20,620	241,150

¹ These totals differ slightly from those in table 1 because they exclude a small number of persons who stated at time of admission that they lived outside the State.

among the counties and communities. Part of this variation is due to the large differences in total population of these units, but even when examined on a rate basis major differentials still exist. In general, areas where population and industry are concentrated have the highest rates. This shows up clearly when communities of the same general size are combined. In cities of 100,000 population the medically indigent and categorical assistance recipients have a far larger number of hospital days per 1,000 total persons than is the case in smaller size communities (table 4). The situation is especially marked in the medically indigent group, with 184 days care per 1,000 population in the large cities as compared with a rate of 32 in cities of 50,000 to 100,000. In the category of general assistance there is little difference between the rates for large and moderate size communities (25 and 29 per 1,000 population, respectively). The big drop occurs when the community size falls below 50,000.

Summary

In considering the possibility of per diem payments for hospital care of the indigent and medically indigent in New Jersey, a 5-week survey of the general short-term hospitals was conducted. Extrapolations of the survey findings

indicated that the annual volume of admissions as general service ward cases of the medically indigent was two to three times that of all public assistance recipients. Highest admission rates per 1,000 persons receiving public assistance were found in the general assistance (164) and the disability assistance (129) categories. Persons 65 years of age or older accounted for about one-fourth of the 12,640 admissions of public assistance recipients and one-fifth of the 32,080 admissions of the medically indigent.

For both public assistance recipients and the medically indigent, the average length of hospital stay was about 11 days, and almost 12 percent of both groups stayed in the hospital for at least 25 days. Hospital utilization by the medically indigent and public assistance recipients increased with size of community. In cities of 100,000 or more persons, the medically indigent accounted for a particularly large number of days in the hospital (184 per 1,000 total population).

TECHNICAL NOTES

All numbers and rates of hospitalization derived from the 5-week survey (March 15–April 18, 1959) are on an annual basis. This was accomplished by multiplying the survey data by the factor 52/5. A special inquiry to the hospitals indicated that in 1958, 18.9 percent of the total number of all admissions (private,

semiprivate, and general service ward combined) took place in the 2 months, March and April, making these months higher than average. (The expected proportion for these 2 months, if there were no seasonality, is 16.7 percent.) However, no adjustment has been made in this study for seasonality since it is not known whether general service ward admissions follow the same pattern as total hospitalizations. From the age distribution of patients, it would appear that general service ward patients are more heavily weighted with older persons and far less heavily weighted with children than the total admission group. This could very well affect the seasonality picture.

The hospitalization rates presented are extrapolations of survey data which refer to the situation that existed in the general hospitals that reported during the study period.

Retirement at 65?

In our society we accept quite as a matter of fact today that retirement begins at age 65. There was a day when some thought life began at 40. Today we have reached a point where many people at 40 are told that to start a second career is foolhardy and impossible. But while we go along accepting age 65 as a magic age for retirement, great advances in medical science and research are gradually increasing the lifespan. It is not unreasonable to assume that in the not too far distant future we will be talking in terms of 100 years for a lifespan. It is also reasonable to assume that people will be in good health and quick of mind far beyond the age of 65, as of course a great many are today.

As the lifespan goes further toward the century mark, can we sit idly by and hold to the present concept of retirement at age 65? I think not.

One researcher recently came up with this analysis. Suppose a worker retires at age 60 and lives to age 70. He has a gift of 31,000 hours of free time which would otherwise be spent at work. If you add to this the hours of free time which we all enjoy on weekends and evenings, his total hours of free time rise to 45,000 hours. This is a quantity of time which is more than all of his previous working hours from the age of 40 to 60. His free time in retirement equals precisely half of his past working life.

In a very real sense this also represents a waste of manpower, talent, energy, wisdom, and intelligence. Sooner or later we as a society must ask

ourselves if we as a Nation can afford this waste.

The Congress, in enacting the legislation calling for the White House Conference on Aging, addressed itself to this question when it stated:

"Outmoded practices in the employment and compulsory premature retirement of middle aged and older persons are depriving the economy of their much needed experience, skill, and energy and simultaneously are depriving many middle aged and older persons of opportunity for gainful employment and an adequate standard of living."

The Federal Council on Aging said in its report to the President dated September 30, 1959:

"A broad-gauged study of compulsory retirement is needed. Retirement practices which force the separation of employees at an arbitrary age level ignore the fact that different individuals of the same age have different capacities and desires. The feasibility of flexible retirement programs needs to be examined."

It might be well for us to recall that Goethe completed *Faust* at 83; Ben Franklin invented bifocals at 78 because he wanted to continue his contribution to his Nation and the world; Helen Keller at 79 is still working for the deaf and blind; Albert Schweitzer is a young 84 now. How do you really feel about retirement at 65?—ROBERT A. FORSYTHE, Assistant Secretary of Health, Education, and Welfare, in a speech delivered at the annual meeting of the Life Insurance Advertisers Association (Eastern Section) in Washington, D.C., March 17, 1960.

Public Welfare Medical Care

LUCILLE M. SMITH

THE NEW JERSEY COMMISSION to Study the Administration of Public Medical Care, created in 1956, has completed and published its report (1). The commission has invited me to present a backdrop for a discussion of its report.

Let me begin by presenting some facts for the Nation as a whole. In March 1959, payments made to suppliers for medical service for recipients of all five categories of public assistance amounted to approximately \$37 million, representing an annual rate of about \$446 million (2). The number of persons receiving assistance in that month was 6.3 million.

Of these payments, 53 percent were made in behalf of old-age assistance recipients. In the four federally aided categories, additional amounts were provided in some States in the form of money payments to enable recipients to purchase medical care, probably more than \$100 million during the year.

Let us, for purposes of perspective, contrast these figures with those revealed in the first national study of welfare medical programs in 1934 under the Federal Emergency Relief Administration (3). In March and April of that year, 17 million persons were "on relief." Expenditures for medical care were \$1,700,000, or 10 cents per person per month. This amount represented from 2.5 to 3.7 percent of all expenditures for relief. In March 1959 the monthly per capita figure was \$5.93 and medical expenditures represented 12 percent of all assistance costs.

Increase in Complexity

These figures reflect not only the general increase in medical care costs but a complex of factors: more use of hospital and nursing home

care today than 25 years ago, more older people in the population, more disabled persons surviving to require long-term care, improved quality of care, and wider recognition of the importance of health services. To fully understand what the commission expects of welfare departments requires recognition of these changes and of experiments and emerging trends in new ways to organize health services.

New Jersey was 1 of 26 States which had a successful program under the Federal Emergency Relief Administration. It was statewide except for Hudson County, which provided care through its public hospital and outpatient department. The New Jersey program had a professional advisory committee, a full-time medical director who served without compensation, and detailed policies and procedures, including fee schedules. Although Federal funds were not then available for hospitalization, New Jersey, like six other States, met these costs from State or local funds.

In a sense, those of us who knew the Federal Emergency Relief Administration feel a nostalgia for the days when there were no categories, no complicated eligibility conditions, and there was only one public welfare medical care program. Although we can't turn the clock back, that early experience confirms the soundness of many of the commission's conclusions and recommendations which are consistent with that successful experience.

It is an understatement to say it will be more

Mrs. Smith is chief of the Health Services Organization Branch, Division of Public Health Methods, Public Health Service. The paper presents the substance of a speech delivered by Mrs. Smith during the 58th annual conference of the New Jersey Welfare Council, November 18, 1959, in Atlantic City, N.J.

difficult to have a successful medical care program in 1960 than it was in 1934. But having been successful once, I am sure New Jersey will be again.

Patterns of Administration

To return to the present era, let us examine the variety of ways in which public welfare medical programs are administered. As of the most recent count, 38 States make vendor payments for some medical care services.

The variation in scope of services ranges from a comprehensive program covering preventive, palliative, and restorative services of all kinds to a program which only purchases drugs. In a sense, therefore, it is a fiction to say that 38 States have a medical care program. Without sufficient scope in the services included, quality of care is not available.

In two States, Hawaii and Maryland, the public health department acts as agent for the State public welfare department. In one State, the department purchases services by contract with the Blue Cross organization which receives and pays bills for certain services on a cost-plus basis in old-age assistance. In the same State, in aid to dependent children and aid to the blind programs, recipients are given Blue Cross and Blue Shield coverage on a pre-paid insurance basis. In another State, the State medical society administers the program for the welfare department. In still another, the State pharmaceutical association acts as agent of the welfare department for the purchase of drugs, and the agency itself purchases all other services. In another State, the physicians' services organization has contracted to administer the plan for the State public welfare department. Thus a few States have moved to transfer partial responsibility for medical assistance to official or nonofficial agencies concerned with the purchase of medical care. The bulk of the public welfare agencies, however, are administering the program themselves, often with little relationship to other agencies which also carry medical care responsibilities.

A Series of Paradoxes

This is one of the many paradoxes in public welfare today. Let's look at some of them.

"Do-it-yourself" has become a popular slogan in recent years for homeowners, but for public welfare administrators it is a dangerous practice. The State medical and dental societies, the State health department, the hospital association, and other health-oriented organizations have a vital role to play in the public welfare medical care program in every State.

Another paradox is the physicians' role in public assistance.

In view of the comprehensive nature of many medical care plans and of the vast sums expended, it has always seemed to me ironical that few States employ medical directors. In addition to the 2 health officers who direct the medical assistance program, only 11 States employ physicians to administer the medical care program. And this in agencies which employ a supervisory ophthalmologist to determine blindness and psychiatrists and internists to determine disability! Moreover, I am told, that in many States the excellent diagnostic information secured to determine eligibility is put to no further use. Medical services purchased are usually remedial—rarely are preventive or restorative services purchased. Thus, we are increasing the number of disabled who will continue to require large sums for their support, including their medical care.

Fortunately, some communities have begun to look for ways in which early diagnosis and treatment services can prevent disabling illness, and at other projects designed to restore the disabled to self-care. Hopefully, the 1956 amendments to the Social Security Act, stressing self-help and self-care, will motivate many agencies to undertake such projects. Let me give you a few examples of demonstrations in California and New Jersey that have proved most successful.

In Santa Cruz County, Calif., the local health department offers a physical screening and treatment program to all old-age assistance recipients who wish to enroll in the program. Costs are met through a combination of ingenious financial arrangements. The welfare department considers the physical screening phase a part of its determination of need and for this reimburses the health department from its administrative fund, thus securing half the cost from Federal funds. The State's medical care

program meets the costs of home and office visits and some drugs. Surgery, drugs not provided through the State program, and dental and ancillary services are financed by local health department funds. This program which has been operating since September 1955 has served 1,501 recipients or nearly one-half the total old-age assistance caseload in the county. Three clinic sessions are held weekly. A distinguished retired physician who serves without compensation conducts the history and physical examination. A public health dentist, public health nurse, and social worker are provided by the health department.

In a paper recently presented to the State directors of chronic disease programs, Dr. Russell S. Ferguson, health officer of Santa Cruz County, described the program in detail pointing out the financial savings as well as the better health which resulted from prompt identification of medical need and a team approach to developing a treatment plan. He concludes that important results have been achieved through this project:

"First, an increased interest by the individual with respect to the future maintenance of his own health achieved by the screening examination and the immediate reference to the physician of his choice. Second, through our mobilization of every financial and community resource we have been able to provide the vendor of medical, dental, and ancillary services and the recipient with means whereby the latter's health may be maintained. Third, we have been able to restore these people to the dignity of private patients in private hospitals for surgical care resulting in impressive savings to the county and restoring to the surgeon his privileged relationship with the patient. Finally, we are convinced that these services can be provided at exceedingly low cost and do contribute to the prevention of long-term illness involving institutional care and the prevention of blindness" (4).

Within New Jersey, following the mandate of the Prevention of Chronic Illness Act, a project was designed in 1955 to make restorative services available to selected persons receiving public assistance. Many of you probably know of the restorative services unit of the Essex County Hospital in Belleville. It was financed

by a combination of State health and county welfare funds and with joint planning by official bodies, seven community hospitals, and the Essex County Medical Society. The focus of this project was on restoration of chronically ill and aged individuals to self-care.

Many of the patients had a long history of hospitalization and most were bedfast or chairborne. Of the 188 admissions to the project, 143 outlived the study period. Of these, 75 percent were bedfast on admission, but only 3 percent were bedfast on discharge. The study documents the savings in dollars, in use of expensive medical facilities, and last but not least in human dignity and self-sufficiency. A report of the study presented before the 1958 annual meeting of the American Public Health Association was prepared by Adriane V. Duffy in collaboration with Marguerite F. Hall. Following the pattern established at Essex County Hospital, this type of professional, technical, and financial assistance is being extended by the State health department to other community hospitals in order that restorative services may be provided as soon as possible after the onset of illness. Such measures are designed to prevent disabling impairments and to minimize the disruption of family life.

Both of the projects described illustrate new trends in public health administration that should be of as much interest to welfare departments as are the recent amendments to the public assistance titles of the Social Security Act concerning matching of expenditures for medical care. The latter made more Federal money available to State agencies and also made possible simplifications in the purchase of medical services for public assistance recipients. They did not—and were not devised—to assure the availability of the highly specialized preventive and restorative services needed by these recipients. More and more, the role of public health departments is being shaped to include this important responsibility. The Santa Cruz and Belleville demonstrations, hopefully, will stimulate other county health and welfare departments to combine resources to get preventive health services to recipients at an early date.

New Jersey is the only State in the Union which has set out to make homemaker service

Recommendations

The following summarizes the Report and Recommendations of the New Jersey Commission to Study the Administration of Public Medical Care. The publication is available from the New Jersey State Department of Institutions and Agencies.

"Organized medical care in the widest sense of the word has come to be recognized as essential to the effective and economical operation of the public assistance system as well as to the welfare of needy persons. There is hardly a more fascinating chapter in the history of social organization of medical care in this country than the story of the progress from repression of pauperism to rehabilitation of the recipient of public aid; from provision of some medical treatment and minimal custodial care to that of a wide range of protective, curative and rehabilitative health services; and from reluctant acceptance of paupers to eligibility of all persons receiving basic income maintenance and increasingly of medically needy people," Dr. Franz Goldmann stated in his book "Public Medical Care" (1945).

The commission believes that it is in the spirit of this statement by Dr. Goldmann that the medical care program for all the needy of the State should be organized and administered. They believe that there is a base on which a good program can be developed but that some realignment is necessary both in administration and financing.

The commission believes the duplication of administration by multitudinous agencies should be abandoned and that the county welfare boards administering the four categories of aid could best be developed as the units to administer all the medical care programs for the needy as well as the medically indigent.

Well-organized comprehensive medical care programs require the advice and counsel of trained medical practitioners who should be assisted by the services of professional medical social workers and other consultants in the allied disciplines representing dentistry, optometry, hospital management, nursing, and others. The medical unit should have the services of technicians to implement special studies.

There should be communication with the professional organizations representing the suppliers of medical, hospital, and allied services through desig-

nated members serving on committees consulting with the professional personnel of the agency.

A comprehensive program should include the gamut of medical, hospital, and allied services any or all of which may be necessary to care for the needs of the recipients. The individual or institution providing the services should be paid directly on a fee-for-service based on a negotiated fee schedule. Hospital rates should be established on the basis of a reimbursable cost formula acceptable to the department and the hospital association.

The present lump-sum appropriation system for voluntary hospitals and nursing organizations should be abandoned as administratively unsound and economically indefensible.

Those persons who are ordinarily self-supporting, but because of illness become medically indigent, should be the responsibility of the county welfare boards on the basis of established criterion of need. This criterion should be established by the board of control of the department of institutions and agencies.

The obligation to repay the agency for medical expenditures should be established for the general assistance recipients and the medically indigent by rule of the department. This obligation should take into consideration the individual's particular circumstance and the burden of high cost medical care, particularly hospitalization.

Financing of hospital care for all those persons who are in need should be borne more equitably by the Federal, State, and county governments. The municipalities will be participating by their contributions to the county tax funds.

The commission believes that a medical care program for those in need and the medically indigent in which the executive officer, the legislature, and the people of New Jersey can take pride is the objective of this study. The program should have a sound legal base and good professional administration so that it fulfills the purpose of serving those in need in a wise and humanitarian spirit.

The success of the program will be determined by the interest and competence of those who have the responsibility for the administration of medical care for those who cannot provide it for themselves.

available to everyone who needs it, and the goal is more than half reached. Now 14 agencies offer homemaker service in 13 counties. Three other counties are working toward establishment of a program. This is another instance in which the health department has undertaken to create the availability of services and in which public welfare participates actively both in planning and in financing the service.

When communicable diseases were the major focus of public health programs, a battery of laboratory, diagnostic, and treatment services were made available to help practicing physicians give good care to their patients. So today when chronic disease is the major public health problem, health departments are developing new techniques of therapy and new methods of organizing health services so that they can offer to the practicing physician the services of public health nursing, medical social work, physical therapy, and occupational therapy which, when coordinated under the physician's direction, will bring long-term patients the kind of care that meets their needs.

Guidelines

To help public welfare agencies arrive at some simple "do's" and "don'ts" in undertaking the very important task which is laid out by the commission's report, let me summarize a few of the "do's":

- Consolidate your local efforts into units of workable size. It is folly to think of 500 local medical plans in the State; 21 is a reasonable number.

- Appoint in each county one or more advisory committees to help develop the county adaptation that will meet the requirements of the State plan and make best use of the local resources. Choose the public-spirited leaders from medicine, dentistry, nursing, social work, and other health interests to help you. Hospital and nursing home administrators and directors of visiting nurse associations are logical candidates for membership. In my judgment, the health officer or his representative is a "must" on such a committee. To balance the health interests, it is well to include representation from industry and labor and the lay public.

- Employ a good medical director, full time wherever practical. In selecting him, do not overlook the physician who has had administrative experience in industry, in group practice, or in the military service.

- Look to the medical society for guidance. Their help is a sine qua non in designing and carrying out practical policies and procedures. At the outset take to them your little problems as well as the big ones so they can know of your failures as well as successes. This will assure that their interpretation of the program to their fellows and to the other purveyors of health services is a true reflection of what the agency means to do and why and how it does so.

- Make a plan for seeing the official publications of national agencies that can keep you abreast of developments in medical care. The journals of the American Dental Association, American Hospital Association, American Medical Association, American Nursing Home Association, American Public Health Association, and the American Public Welfare Association all carry articles of value to administrators of public welfare medical care programs. The same is true of the *Social Security Bulletin* and the Public Health Service's *Public Health Reports*. Two less technical publications which the American Medical Association publishes for free distribution have real value for you—*The AMA News* and the *Chronic Illness News Letter*. Shortly, the AMA will begin publication of a *Bulletin on Homemaker Services*.

The American Public Welfare Association has a series of publications specific to the administration of public welfare medical care programs, "The Physician in the Public Welfare Agency," "The Medical Social Worker in the Public Welfare Agency," "Self-Evaluation Schedule for Medical Assistance Programs," "Improving the Quality of Tax-Supported Medical Care," and "Medical Care in Public Welfare" (report of Institute III), to mention only a few. All of these are for sale by the association at a modest price.

- Plan for at least an annual meeting where medical directors can share their experiences. A group council such as the New Jersey Welfare Council provides a readymade vehicle for such sessions.

- Encourage your medical directors to at-

tend regional meetings of the American Public Welfare Association and the biennial round-table so they can talk with their counterparts in other States.

There are a few cautions I should like to advance in the "don't" column:

- Don't regard the medical assistance program as merely a purchase-of-service program. It is much more than that. Be concerned with health maintenance and health promotion. Give serious consideration to the evaluation of present services and redirection when indicated. Make use of diagnostic records to plan with recipients for the treatment they need.

- Don't allow the costs of hospital and nursing home care to cloud your vision. In my judgment, preoccupation with these two types of service prevails throughout the entire United States in spite of the fact that most people who are ill or disabled are at home and prefer to be cared for there. Give services for patients at home a high priority.

- Don't work in isolation. Especially learn the differences in philosophy and objective of other official agencies like the health or rehabilitation departments and develop a systematic method of cooperation with them.

- And, finally, don't be discouraged. You are on the eve of one of the most exciting tasks you will ever have. I once organized a local medical care program with the active help of all the organizations I have mentioned. It took about 9 months to develop basic policy and procedure. They were the most rewarding months of my life. I had more help from more people than in any corresponding period of my 35 years of work. I wish you the same good fortune.

Community Health Administration Studies

During the past several years, the W. K. Kellogg Foundation has awarded grants to three State health departments (California, Florida, and Washington) and to the schools of public health of three universities (Johns Hopkins, Michigan, and Toronto) for development of studies in community health administration. From these studies the Foundation hopes will emerge new relationships and patterns of public health practice for both the schools and the operating agencies.

Directors of the studies held their first meeting in Washington, D.C., on March 17 and 18, 1960. The meeting was sponsored by the Foundation to provide an opportunity for exchange of viewpoints and experience and to discuss common problems. H. H. Hasson, associate director of the division of medicine and public health of the Foundation, requested Dr. William F. Mayes, assistant chief, Division of General Health Services, Public Health Service, to assist him in planning the meeting and to serve as its chairman.

Social Science in Family Medical Care

ELIOT FREIDSON, Ph.D., and GEORGE A. SILVER, M.D.

THE CHANGES taking place in medical practice all over the world are reflected both in medical knowledge and in the roles of professional workers associated with the techniques of medicine. Efforts to reconstruct a stable system of medical care appear to stem from a number of objectives.

Most people would agree that any system of medical care should first make full use of all the modern knowledge and equipment available to produce the scientifically accurate diagnosis and treatment we call good care. It should offer a worthy and dignified role as well to the professional practitioners who are to provide that care. Also, and by no means to be taken as academic, it should be so constituted that prospective patients will choose to take full advantage of the benefits offered by such care.

There is general agreement on these objectives. But a controversy hinges on the form of organization by which they may be achieved.

This report describes an experiment in medical care that sought to fulfill these objectives, some of the findings of the study of that experiment by a social scientist, and the way in which these findings may aid in reformulating the organization necessary to achieve full use of such medical care by the public.

Family Health Maintenance Demonstration

At the Montefiore Hospital in New York City, there has been in operation since 1950 a program of comprehensive medical care on a prepayment basis for 150 families. Services are given not by individual practitioners of the various specialties, but instead by a functioning

health team composed of an internist, a pediatrician for children under 13 years of age, a public health nurse, and a social worker. This is the Family Health Maintenance Demonstration (1,2). The families were selected at random from a large group of those insured under the Health Insurance Plan of Greater New York (3). The health team gave the family a baseline examination, conferred with the family on the findings, and supplied comprehensive medical care over a 4-year period. At the end of the 4-year period, the team made a second evaluation of the family's health.

Comparable data were also obtained for a matched control group, substituting the services of individual practitioners from the Montefiore Hospital medical group for the demonstration health team. The demonstration originated within this medical setting. In essence this was a controlled experiment on the effect of an organized medical care program on health. The study families were given team-organized services while the control families continued to use the individual services of the medical staff of the Montefiore Hospital medical group, and the health of both groups was assessed in the same way at the end of the program.

Part of this experiment was designed origi-

Dr. Freidson is assistant professor of sociology, the City College of New York, and Dr. Silver is chief, division of social medicine, Montefiore Hospital. Dr. Silver was director and Dr. Freidson, consultant, in the Family Health Maintenance Demonstration. This paper was read at the Fourth World Congress of the International Sociological Association, Stresa, Italy, September 1959.

nally to determine what health education and promotion techniques would influence the health of families favorably if added to health programs (1). Of course, arbitrary criteria were used to define "health education," "health," "favorable," and the like. Health, for example, was defined as capacity to function successfully in four major areas—work, sex, play, and family life. By these criteria, it was found that the program was not successful in improving the health of families. At the same time, however, team organization of medical care was successfully demonstrated and seemed highly satisfactory to the patients.

The Role of Social Science

The social scientist could take no active or manipulative role in the demonstration. By its controlled nature, changes could not be introduced. Instead, the social scientist sought to study, in a broad, exploratory way, the relation of the organization of medical practice to the behavior of patients. Attention was concentrated on the patients' conceptions of professional practitioners and the processes by which the patients use the services. Through this study, hypotheses were developed about the conditions under which professional services could be used, based on a theoretical framework which stems from communications research and anthropological conceptions of the community.

Analysis of the findings seemed most appropriate within the context of an organized process of interpersonal influence similar to that described by Katz and Lazarsfeld (4). The process seems of particular significance when the patient is uncertain, as on occasions when he must select a new doctor, or when he uses a doctor for the first time, or when he is undergoing mild suffering from ambiguous symptoms and cannot decide how his illness should be treated or whether he should consult a professional practitioner about it. Whether or not this uncertainty occurs is, of course, largely the result of the culture or knowledge of the patient. But when it does occur, the course taken seems to be determined by the lay culture in which he lives and the network of lay and professional consultants to whom he turns for help. We have chosen to label this the "lay re-

ferral system." The lay referral system is paralleled by the professional referral system, with its own culture and network of consultants and colleagues.

Use of Services

The primary objective of the Family Health Maintenance Demonstration was to experiment with team organization of health services (5). It became clear rather early that one member of the professional team, the social worker, was not being consulted to the degree considered appropriate by professional standards. This was not due to a lack of personal problems in which a social worker could assist, since members of about one-third of the families were recognized as having such problems. Neither was it due to the patients' failure to recognize that they had such problems, for they did seek help from other team members.

Research by intensive interview and questionnaire suggested that the role of the social worker in the team was both culturally and structurally isolated from the lay referral system (6). The patients seemed to avoid using the social worker because her professional role was segregated not only from medical problems but also from such everyday affairs as nutrition, housing, and the children's schooling. In consequence, the social worker came to be defined by the patients as a specialist rather than an everyday consultant. Functionally, a specialist is consulted only after exhausting more commonplace resources. In avoiding the social worker and seeking the aid of the public health nurse and the physician for their personal problems, the patients were in essence seeking less specialized aid.

Thus it was hypothesized that because of the cultural background of these patients, early use of the social worker as a preventive measure could be expected only if her role were changed to more closely resemble, for example, that of the public health nurse, which was more informal and more concerned, on the surface at least, with the manifest medical, economic, and interpersonal affairs of everyday life. This role was subordinate to and chronologically was used prior to that of the physician in the process of defining illness and seeking

aid, standing as it did between that of the physician and that of some such lay consultant as a relative or friend. However, if the social worker's role was not changed and if the patients' culture remained unchanged by an educational campaign, it was concluded that the social worker would be used primarily by those few who believed themselves to have exhausted "ordinary" sources of help, and thus conceded the "special" nature of their problem.

Use of the social worker reflected the organized process of seeking help stemming from the concept of the lay referral system. This was also seen to be the case in the use of medical services.

Eleven percent of the families (13 of the 117 responding) reported that some member of the family at his own expense had a surgical operation performed or a child delivered by an independently practicing physician while the family was enrolled in the demonstration and was entitled to this medical care under the terms of its subscription. For more everyday, nonsurgical services, 6 percent of 119 families indicated that some member had used the services of an independent practitioner "quite a bit," and an additional 31 percent reported that an independent practitioner was used "occasionally" at out-of-pocket expense.

But an overwhelming proportion of patients were far more satisfied with the health team organization of care than with care received from individual practitioners, either in group or independent practice. Ninety-two percent of the families responding believed that the health team demonstration was more beneficial to them than care received from the Montefiore Hospital medical group, and 85 percent concurred in approving the health team when comparing its care with that received from their prior "private doctor." Also 94 percent stated that it was more pleasant to be a Family Health Maintenance Demonstration patient than to be a Montefiore Hospital medical group patient, and 74 percent stated that it was more pleasant to be a demonstration patient than to be the patient of a "private" doctor outside either scheme.

There seems to be a contradiction in these data. If so many patients believe that the

demonstration is beneficial to their health and pleasant to use, why did one-third of them use outside services? On the whole, and we must compress a good deal of data here, two things seemed to be involved in the use of outside services—the patient's assessment of the quality of medical care available to him and his assessment of the importance of his medical complaints. In what seems to be the bulk of the instances of use of outside services, the patients assessed their complaints as minor, and assumed that for minor complaints any physician is competent. Under such circumstances, simple convenience seemed to dictate the occasional use of a neighborhood, independent physician rather than the demonstration physician at the centralized medical group. This was particularly the case for home calls at night when the demonstration physician was unavailable, and other physicians of the medical group were on call in rotation. In this situation, of course, the ability to pay the fee of the independent practitioner is an important element. It was found, in fact, that the use of outside services increases in general as social class, and its contingent ability to pay, rises.

Where just convenience is involved and the illness does not seem to be critical, typically the patient acts as an individual, without interaction with lay consultants. This is not the case in more analytically interesting instances when the patient feels some anxiety about the illness and becomes uncertain about the qualifications of the physicians involved. On these occasions, the relationship of the lay referral system to the professional referral system becomes quite important.

Analysis of instances of the use of outside service, probed during intensive interviewing, has not been completed. But at present it seems that the necessity to use a specialist rather than the everyday family health maintenance physician, whether for surgery, child delivery, or special therapy, seems to be common to all instances that do not rest on sheer convenience. These were cases where referral from the demonstration to a Montefiore medical group specialist was not sustained. And, by definition, these were cases where referral implied the illness was serious. In these cases,

nally to determine what health education and promotion techniques would influence the health of families favorably if added to health programs (1). Of course, arbitrary criteria were used to define "health education," "health," "favorable," and the like. Health, for example, was defined as capacity to function successfully in four major areas—work, sex, play, and family life. By these criteria, it was found that the program was not successful in improving the health of families. At the same time, however, team organization of medical care was successfully demonstrated and seemed highly satisfactory to the patients.

The Role of Social Science

The social scientist could take no active or manipulative role in the demonstration. By its controlled nature, changes could not be introduced. Instead, the social scientist sought to study, in a broad, exploratory way, the relation of the organization of medical practice to the behavior of patients. Attention was concentrated on the patients' conceptions of professional practitioners and the processes by which the patients use the services. Through this study, hypotheses were developed about the conditions under which professional services could be used, based on a theoretical framework which stems from communications research and anthropological conceptions of the community.

Analysis of the findings seemed most appropriate within the context of an organized process of interpersonal influence similar to that described by Katz and Lazarsfeld (4). The process seems of particular significance when the patient is uncertain, as on occasions when he must select a new doctor, or when he uses a doctor for the first time, or when he is undergoing mild suffering from ambiguous symptoms and cannot decide how his illness should be treated or whether he should consult a professional practitioner about it. Whether or not this uncertainty occurs is, of course, largely the result of the culture or knowledge of the patient. But when it does occur, the course taken seems to be determined by the lay culture in which he lives and the network of lay and professional consultants to whom he turns for help. We have chosen to label this the "lay re-

ferral system." The lay referral system is paralleled by the professional referral system, with its own culture and network of consultants and colleagues.

Use of Services

The primary objective of the Family Health Maintenance Demonstration was to experiment with team organization of health services (5). It became clear rather early that one member of the professional team, the social worker, was not being consulted to the degree considered appropriate by professional standards. This was not due to a lack of personal problems in which a social worker could assist, since members of about one-third of the families were recognized as having such problems. Neither was it due to the patients' failure to recognize that they had such problems, for they did seek help from other team members.

Research by intensive interview and questionnaire suggested that the role of the social worker in the team was both culturally and structurally isolated from the lay referral system (6). The patients seemed to avoid using the social worker because her professional role was segregated not only from medical problems but also from such everyday affairs as nutrition, housing, and the children's schooling. In consequence, the social worker came to be defined by the patients as a specialist rather than an everyday consultant. Functionally, a specialist is consulted only after exhausting more commonplace resources. In avoiding the social worker and seeking the aid of the public health nurse and the physician for their personal problems, the patients were in essence seeking less specialized aid.

Thus it was hypothesized that because of the cultural background of these patients, early use of the social worker as a preventive measure could be expected only if her role were changed to more closely resemble, for example, that of the public health nurse, which was more informal and more concerned, on the surface at least, with the manifest medical, economic, and interpersonal affairs of everyday life. This role was subordinate to and chronologically was used prior to that of the physician in the process of defining illness and seeking

fectiveness increased by adding the benefits accruing from more extensive training in case-work and psychiatry. The day-to-day team would thus be smaller, composed of two physicians (one for adults and the other for children) and the public health nurse. The social worker, however, might continue in close liaison with the team, but not on a full-time basis: she could represent the first echelon of referral for emotional difficulties in those families which recognize and accept the fact that psychiatric care is required.

Finally, it might be said that both the demonstration and the findings of the social scientist in his study of it have had important and encouraging implications for social policy. The popular fear of governmental or private large-scale medical service in the United States seems to be based on the fear of loss of personal attention in a bureaucratic setting. Team practice, as it was observed in the Family Health Maintenance Demonstration, seems to provide the attention desired, even though the setting is bureaucratic, since the patients expressed a high degree of personal satisfaction with the care they received.

A notable aspect of this satisfying team action was the family conference, an annual, hour-long discussion between parents and professional team members which seemed to allay suspicion, deflect hostility, and offer a unique opportunity for the exchange of information. If such team practice could be integrated into

the informal conferences that take place between patients and their lay advisers, it might be possible to allay even those instances of suspicion occurring when patients are referred to specialists in a bureaucratic setting.

Research in Health Departments

A regional conference on the opportunities for research in local and State health departments, sponsored by the Public Health Service, drew representatives from six States to Atlanta, March 14-16, 1960.

The conference included a demonstration of the operation of a study section, reviewing grants applications, with reference to specific projects or research proposals. The study section members benefited no less than the audience from the discussion. The need for communication guiding information from the National Institutes of Health to the principal investigators and applicants was emphasized repeatedly.

It was the consensus that such conferences in other regions would be helpful to health officials.

the diagnosis or the referral or both were questioned by the patients, and, in the course of seeking alternative diagnoses or of validating the competence of the specialist to whom they were referred, they were led outside the medical group.

This difficulty in professional referral seemed to stem in part from the very mode in which medical care was organized. The patients rightly viewed the Montefiore Hospital medical group in which the demonstration operates as a cooperative organization. In this sense, when their demonstration physician referred them to a medical group specialist, they believed that the referral was necessarily to the man who happened to be working in the medical group, and not necessarily (but of course possibly) to the so-called best man in the field. The patients who went outside wanted what they believed to be more disinterested validation of the quality of the physician to whom they were referred. Disinterested sources of validation, however, are also outside the professional organization of the group—"private" physicians and the lay community. In those few cases recorded where temptation to use outside services existed but was resisted, the patients happened to obtain recommendations of the group specialist to whom they had been referred from lay consultants who knew the work of the specialist or, in one case, from an independent "private" physician. The major source of such validation of professional quality appears, in fact, to lie in the lay referral system, so that we may expect those patients whose lay consultants do not know the reputation of the medical group physicians to be subjected to interpersonal forces that encourage the use of outside physicians. Some statistical evidence to support this conclusion has been gathered.

On the basis of these exploratory findings, it was hypothesized that a medical care organization has a better chance of holding its patients through all contingencies if the patients interact with each other in inclusive natural networks of interpersonal influence. Where patients are unknown to each other and yet they participate in a number of lay referral systems the bulk of whose members have no experience

with the medical organization in question, it is to be expected that use of the service will be diminished to some extent.

Application of the Findings

As Katz and Lazarsfeld have shown (4), the concept of personal influence has relevance to sociometric and small group studies. We may add that it also underscores the relevance of comparing anthropological studies of "little communities" (7,8) with studies of urban aggregates (9). The concept of the lay referral system allows us to consider simultaneously the culture, or "health education," of the patient, his participation in a highly influential network of lay consultants, and, finally, the structured relations which exist between the lay and professional worlds. This relevance is most extensive in instances where patients have a considerable latitude of choice between practitioners, a situation characteristic of some parts of the United States but not of some other countries (10,11). It is also relevant to any medical system where the patient may at least choose not to use available medical services at all (12).

In the program described here, however, and in future plans for similar programs of research in modes of family health care, a number of implications have emerged. First of all, it may be observed that the picture of society that it gives us is one obviously incompatible with viewing the patient as an isolated individual or even as a member of an isolated nuclear family. In future experiments with the organization of medical care, it seems that we must deal with the patient as a member of a network of interpersonal influences. This means that a fruitful source of study populations may lie more in such networks than in individuals selected at random. A selection of such networks should also include the members of the network to whom others would naturally turn for medical and personal advice and guidance. After influencing these "influentials," health education may not continue to be unsuccessful in modifying behavior, and, as hypothesized, patients might be more thoroughly "held."

In a future program, it seems also that the social worker need not be used as a primary teamworker. The public health nurse's role could be exploited to greater effect and her ef-

The Sweep and Excitement of Science

JOHN R. PLATT, Ph.D.

THE tremendous interest of the public in science today, I think, can be attributed to two main factors. One is the headline role that technology is now playing in war and in public affairs. It inspires readers to learn more, uniting their curiosity with good citizenship. But much of our fascination is also due to the skill and devotion of teachers and writers, editors, and broadcasters, who are trying to present the story of science to the mass audience and to explain in simple terms just how atomic piles, computers, and satellites work and what they mean. Interest feeds on explanations. The more we get, the more we want, from 4 years of age onward.

Science no longer needs to be explained just to laymen and citizens and children; it now needs to be explained to statesmen and philosophers and even to scientists themselves! The poor scientist can never keep up with the hundred thousand research papers that are published every year, and so he becomes a layman too, in every field but his own, and an important part of the mass audience. There will have to be writing up as well as writing down. There is a need and an audience at every level of sophistication from the nursery school to the graduate school.

What shall we give these audiences? Everyone has his own recipe, but I am sure we are all agreed today that quiz-show facts are not enough. I once heard an English chemist

criticize another English chemist by saying, "That man knows more facts that are almost right than anyone else in the world." Perhaps the American public knows more facts that are almost right than any other public in the world.

But even if the facts are right, the public needs something larger if it is to understand what science is all about. There are three particular qualities of basic science—not technology but basic science—that I think a citizen in a scientific society should be shown over and over until he begins to feel them for himself. The first quality is the excitement of science, the second is the sweep of science, and the third is the incompleteness of science.

Excitement

To say that basic science is exciting may sound like a contradiction. We are used to the really spectacular excitements of the engineers with their radar and rockets; and the life-and-death excitements of the doctors, the biological engineers, in their white coats. By contrast, the intellectual excitement of a man sitting over a microscope in a university basement tracking down a clue may seem pretty tame. But I would remind you that there are two intellectual excitements that are not tame at all and that we remember all our lives. One is the thrill of following out a chain of reasoning for yourself; the other is the pleasure of watching several strongly individualistic personalities argue about their deepest convictions. That is to say, the thrill of a detective story and the pleasure of watching a play by George Bernard Shaw. I would claim these are exactly the excitements basic science has to offer.

Dr. Platt, professor of physics, University of Chicago, delivered the address from which this article was taken before the Thomas Alva Edison Foundation meeting on "The Mass Media and the Image of Science" in Washington, D.C., November 6, 1959.

Health Television Series in Twelfth Year

IN DECEMBER 1959. Baltimore's health information television series, "Your Family Doctor," began its 12th consecutive year. The series, commencing December 15, 1948, is not only the oldest continuously produced medical television series, but now has one of the longest consecutive runs for a television series of any type. From this, one may infer a sustained viewer interest and demand for health information through television.

On a surprisingly small budget, the Medical and Chirurgical Faculty of Maryland and the Baltimore City Health Department have presented more than 550 programs in this series. Cooperation by many interested groups has kept production costs low. Broadcast time and facilities are contributed by station WMAR-TV. Civic organizations regularly provide speakers, panel members, and actors. A Boy Scout group, *upper right*, participated in a pre-Christmas "Home Safety" show, and an American Red Cross swimming class, *center*, in an early summer "Swim Safely" program.

Health directors who contemplate producing a television series or a single program may obtain information regarding the availability of source materials from the World Health Organization, Division of Public Information, Palais des Nations, Geneva, Switzerland; from the Pan American Sanitary Bureau, 1501 New Hampshire Avenue NW., Washington 6, D.C.; from the Public Inquiries Branch, Public Health Service, Washington 25, D.C.; or from the Bureau of Health Education, American Medical Association, 535 North Dearborn Street, Chicago, Ill. Sample scripts used in the Baltimore series may be obtained by writing to Dr. Huntington Williams, Commissioner of Health, Baltimore City Health Department, Baltimore 3, Md.

 GUESTS WORTH Good afternoon, I'm Dr. Worthington and my
 guests are Mr. and Mrs. Philander Rice

ple who get paid for doing exactly what they like are physicists and baseball players. When the word leaks out to the children, there will not be laboratories enough to hold the budding scientists.

Sweep

The second quality to get across to the mass audience is the scope or sweep of science. By this I mean the great range of problems covered, the range of the methods of work, and the wide range of the implications. For illustration I have selected three areas which show very different patterns of development today. One of these is biophysics, the second is what is called molecular biology, and the third is some of the recent work on evolution.

Biophysics is one of the border areas of physics. It is one of the active fronts that have radiated out from the atomic physics of 30 years ago. In one direction these fronts include the new and rich and spectacular sciences of space physics, nuclear physics, and solid state physics. In the other direction, the activity runs instead along several of the borderlines with the older disciplines, giving us the somewhat quieter fields of chemical physics, biophysics, and psychophysics, all of them largely confined to the university laboratories.

These latter areas are not sharply separated. I myself started out in chemical physics, studying the light absorption of dyes and similar molecules. I found that this led me to a study of chlorophyll which was a biological molecule and therefore biophysics. And then it led me to a study of the visual pigments of the human eye, which are the first elements struck by light in the psychological act of vision, and therefore psychophysics.

Biophysics proper is not what I call an exploding field at present but one that is just simmering along nicely. An important area of study lately has been the transfer of light energy between neighboring biological molecules. Many workers feel that such a transfer might be the first step in vision and the first step in photosynthesis, as well as the first step in the damaging of tissue cells by nuclear radiation. This makes it a hot subject and numerous international conferences on it are being held.

My only regret is that some people have chosen to call the subject "bioenergetics," which makes it sound more like a branch of naturopathy than a field of science.

Although the subject of energy transfer is of wide interest, the actual results are rather tenuous, partly because the experimental work has to be exceedingly painstaking. During a summing up session at the Brookhaven conference on this subject recently, the participants listed roughly a dozen new physical instruments and tools that they wished could be invented in order to facilitate work in this field. For example, methods are needed that would permit us to observe or infer the first chemical reaction steps of many biologically important molecules, including the primary molecules in vision, in photochemistry, in genetics, and the antibodies. Conceivably such methods of observation will evolve out of the fluorescence-interaction methods of Michael Kasha, or the tracer technique of Melvin Calvin, or the recent ingenious substitution technique of Engleberger and the Koshlands, or out of a completely new approach. The question remains open. Work is in progress.

Biophysics merges into a closely related area that today is anything but placid, the area of molecular biology. It has had an explosive development in the last 10 years. It was notable first for the numbers of physicists, chemists, and doctors attracted into it by such inspiring microbiologists as Salvador Luria and Max Delbrück. Now it is the scene of the last two Nobel Prizes in medicine, the one to Joshua Lederberg, George Beadle, and Edward Tatum, and one to Severo Ochoa and Arthur Kornberg. And sitting at conferences, one watches with pleasure and astonishment the beautiful demonstrations of the other theorists and experimenters, wondering which of them will be next to get the prize.

Will it be James Watson and F. H. C. Crick, with their two-strand model of the DNA molecule so thoroughly proved in the last few years? Will it be Meselson and Stahl, or Taylor, Woods, and Hughes, with their beautiful tracer methods of testing the model? Will it be Seymour Benzer, with his analysis of microgenetic characters a thousand times finer than any ever

Moreover these intellectual thrills in science are not something distant or alien, but something closely continuous with our everyday thinking. It is true that science is complex. This is because so many men have been building it up for so long. Nevertheless every individual step in it is a little inference as simple as looking out at the weather and deciding whether or not to take a raincoat. When we look at a celebrated rocket engineer like Werner von Braun, we see a man running a big complex organization and dealing with incredible horsepower. But when we look at a fundamental scientist like James Van Allen, the university professor whose tiny satellite equipment detected the radiation belts around the earth, fundamentally what we see is a man stepping to the door of his planet to see how the temperature is outside.

What is essential in any science story is the little chain of everyday inference, the reasoning. It may surprise many people to know that the chain of new scientific reasoning in a whole research study is frequently less complex than an everyday business decision or a crossword puzzle or a game of chess. It would have a salutary effect on our attitudes if for 24 hours we could cross out the words "science" and "scientist" wherever they appear, and put in their place the words "man reasoning." Even in the mathematical sciences, like physics, it is the reasoning that comes first, the equations second; and the equations will not save the theory if the reasoning is wrong. It cannot be said too often that science is not mathematics, but reasoning; not equipment, but inquiry.

The master at demonstrating reasoning to a mass audience was Conan Doyle. It would not be far wrong to think of every science story as his kind of detective story, with its puzzles and its suspense, its false leads and frayed tempers, and its brilliant Sherlock Holmeses, its half-brilliant Inspector Lestrades, and its admiring Doctor Watsons. It is interesting to remember that Galileo himself used a very similar group of characters to explain his reasoning to a mass audience. Science is the greatest of all detective stories, a continued yarn that holds its audience for life, with the disagreements of the characters

nowadays just as conspicuous and as amusing as ever.

The second excitement in the science story is the excitement of personalities. Biography and belles-lettres have hardly touched the field of science. There is valuable literary work to be done here. We need a good biography of G. N. Lewis, whose department at Berkeley turned out half of the best physical chemists in America. We need one of William Moffitt, the witty and brilliant theoretical chemist at Harvard, whose death last year at 33 was a loss far greater than the loss of any headlined baseball player or movie star. We need to put our senior teachers, James Franck of Chicago and Joel Hildebrand of California, and Percy Bridgman of Harvard, on Caedmon records, like poets, for posterity. There are many stories to be found in the sequences of brilliant teachers and brilliant pupils; my own department is fond of pointing out that three Nobel Prize winners this year and last got their Ph.D.'s with Fermi at the University of Chicago.

There is more unusual material, too, such as the story of the Hungarian-American scientists so brilliant that the others call them the "men from Mars." Or the story of such a man as Leo Szilard, a strange and contradictory thinker, who has surely influenced history by his unique role in starting the atomic bomb project as well as by his pioneer landmark papers in a dozen fields. The lighter material would include the amusing yarns that all scientists know about the hobbies of their favorite personalities. There are the mountain climbers; and Luiz Alvarez' parlor tricks; Richard Feynman's lockpicking; Arthur Roberts' musical compositions; and the insults, and the jokes—like the story of the Hungarian who had a sign over his desk that said "Being Hungarian is not enough."

And there are not only past stories, but future stories in the making, the men who may get the Nobel Prizes next year, and the year after.

When the stories of these personalities in science begin to be told, I suspect that we will find that all the men have one common characteristic: they are having fun. And the fun will be contagious. It has been said that the only peo-

Incompleteness

The intelligent layman should be told of a third quality, the incompleteness of science.

All science has gaps in it. The most familiar are the inevitable small gaps, the data that one could still go on taking, the unexamined minor assumptions, or the unresolved questions. Most of these do not bother us because we realize that a scientific age is an age of tentative conclusions and working rules that may well have to be changed later. Yet it is important for us to emphasize this incompleteness, especially to the young, because they have hopes and aspirations and they want an open-ended story, with something left for them to do when they finally take our places.

What is not so often realized is that science is incomplete in more serious ways, with gaps that scientists themselves, tied to their own narrow specialties, hardly realize the existence of. In some ways, for all its diversity, science is narrower now than it has ever been before. Few of the men who work on photosynthesis know anything about physics; few of the men who work on nervous tissue know any organic chemistry; few of the men who work on the brain have any understanding of the mind. There are exceptions. An Enrico Fermi or Edward Teller or Harold Urey can work on stars or nuclei or molecules, just as his fancy strikes him. A John von Neumann can work on quantum mechanics as well as the theory of games. A Percy Bridgman can work on solids as well as logic. But for every such man, there are hundreds who spend their lives repeating the kind of experiments they did for their doctor's degree.

Even the intellectual leaders are blind to some fields. For over a century, some of the greatest physicists, Young and Maxwell and Helmholtz and Schrodinger, thought it of the greatest importance to study human visual perception. Today, I daresay not one of the twenty leading physicists in this country would have even a casual interest in this subject. Likewise, interest in the philosophy of physics has dropped almost to zero among the bright young men; yet this field may simply be waiting for a new Ernst Mach who will stir it up and pave the way for another revolution like relativity. And we have

all noticed such blind spots in the more technical fields, where it has suddenly been discovered, for example, how badly everyone has been neglecting oceanography, an area perhaps of central importance for our future food and resources.

I think these gaps cry out for reviewers and critics broadly trained and broadly read, who are competent to see what the neglected areas are and to encourage the young to go into them. A balanced and vigorous science requires a balanced and vigorous criticism. To paraphrase Clemenceau's remark that war is too important to be entrusted to generals, science is too important to be left to the scientists. Intelligent outside evaluation is good for a department, it is good for a university, and it would be good for science itself. The incompleteness of science is a challenge to great criticism. It is a challenge which I think will be met in the very finest presentations of science to the public.

The Life of Man

It is a thrilling thing to be participating as actor or observer in the scientific revolution of our times, as science enters and transforms the life of man. Some are depressed by the hard work that must be done to make a world, and by the constant threat of failure and catastrophe. Some say philosophy has failed. I think this is only a momentary lapse between the old philosophy and the new that rises already in the laboratories. I think this century marks in history a revolution in man's outlook even more profound, if possible, than the accompanying revolution in science and technology. Man has suddenly found himself. He has explored all the earth and stepped outside it. He taps the sun's source of energy and stands ready to manipulate the weather and use the oceans. He measures back to the beginnings of time and out to the ends of space and sees his own sudden emergence, a thinking creature spun out of light and air and water and holding power in his hand, yet probably only one of millions of such creatures on other worlds.

And the power man holds is not only technical power but something far greater still, evolutionary power. He creates new species of plants and animals, halts or speeds up evolution, ma-

examined before? Will it be Cy Levinthal or some of his competitors, racing to see who can crack the great cryptogram, the code that translates the DNA molecule into the other cell materials? Or Theodore Puck, with his method of culturing perfect tissue cells? Or Albert Coons, with his fluorescent method of labeling antibodies?

The shrewdness of such men in reasoning and experiment has brought a new atmosphere to biology. Needless to say, the older scientists are not entirely sympathetic. Oversimplification, they snort. One eminent gentleman said, and I quote: "You know there are scientists, and there are people in science who are not doing science at all. We need their auxiliary work—they build apparatus, they make minor studies—but they are not scientists."

To which the young microbiologist replies: "Well, there are two kinds of biologists, those who are looking to see if there is one thing that can be understood, and those who keep saying it is very complicated and that nothing can be understood."

Sixty years ago when Pasteur was also trying to see if there was one thing that could be understood, the audience hung breathless on his results. I think this could happen again today. At any rate, molecular biology is, next to nuclear physics, the most intellectually exciting field for a young person to enter at the present time.

A third area, still more biological, is that of the recent work on evolution discussed at the Darwin Centennial Celebration this past fall at the University of Chicago. This celebration honored the 100th anniversary of publication of "Origin of Species." Several of the papers offered dramatic new illustrations of the Darwinian principle of evolution. One of these by Nicholas Tinbergen demonstrated that it is not just bones and muscles that evolve but also behavior, and he gave numerous examples of such evolution as found in the behavior of birds that nest in cramped and dangerous places.

In another paper, F. Clark Howell and Sherwood Washburn showed from the study of old skulls that man's brain has increased in size rapidly since he began using tools and fire, and is now almost three times as large as it was

then. Another study, by Cesare Emiliani, showed that this evolution of our brains may have taken a time much shorter than anyone has supposed, only a few hundred thousand years according to new geological dates. In short, intelligent man, as we know him, may have developed with dramatic suddenness as a result of using his hands to manipulate the world around him. Perhaps we are still developing at the same remarkable rate. It was better brains that determined which of the man-creatures would survive then; and it is better brains that will help us to survive now, we hope.

At the Darwin conference there was also much said about man's population problem today, which is a terribly timely aspect of evolution. There was something like a three-cornered debate on population, between the grandson of the founder of evolution, Sir Charles Darwin; the biologist, Sir Julian Huxley; and another Nobel Prize winner, H. J. Muller. Darwin says that in 50 to 100 years, the overcrowding of our increased population will destroy our civilization forever, and cannot be reversed, because people and groups who want to have many children will go on having them, whether it is good for the whole community or not. Huxley is more optimistic and thinks the population explosion can be stopped if we are intelligent enough to find incentives for stopping it. And Muller says that it is already urgent for us to take really dramatic steps, that is, to begin selective breeding, if we want civilization as we know it to continue.

All three men are united as scientists in saying that we are doomed if we do nothing to reduce our birth rates; they differ only in how much they think, as hopeful men, that we can do nationally and internationally about the problem. Many people may not approve of scientists offering to give their scientific knowledge and counsel to human affairs in this way, just as many people did not approve of the theory of evolution itself a century ago. But I think that the reporter who has the courage to try to transmit this population debate to the public in a full and fair way may find that he has a story as exciting, as controversial, and finally as important to history, as the debate over evolution itself ever was.

Research on Cancer Viruses

JOHN R. HELLER, M.D.

THERE IS NO DOUBT that virology now holds great promise in research efforts on the cause and prevention of cancer. Virology has but recently attained this high status. Only in the past few years has the accumulated evidence of a half century of investigation proved sufficient to convince the more skeptical scientists that viruses cause cancer in animals.

The French bacteriologist Amédée Borrel was the first to make the suggestion, in 1903, that cancer might be a viral disease. His countryman, the eminent virologist Charles Oberling, later pointed out in "The Riddle of Cancer" that Borrel reached this conclusion when he failed to find the "microbe of cancer." For years his idea was defensible "mainly because no other offered a satisfactory interpretation."

Then, in 1908, the Danish scientists V. Ellerman and O. Bang succeeded in transmitting leukemia from one chicken to another by injecting cell-free filtrates of blood and organ extracts. At that time, however, leukemia was not generally considered a neoplastic disease, so their work did not receive much attention.

Two years later, Dr. Peyton Rous, working at the Rockefeller Institute in New York, transferred certain spontaneous tumors of chickens by cell-free filtrates. One of these neoplasms was the source of the Rous sarcoma virus. This work was viewed with some skepticism because of the prevailing opposition to an infection theory, but subsequent work established beyond any doubt that these were true neoplasms and that there were no living tissue cells in the

filtrate. Now we know that Rous' discovery marked an important stage in the history of experimental cancer research. The Rous sarcoma dramatically progresses in degree of malignancy through successive passages in the laboratory, either by cell transplants or tumor filtrates (fig. 1).

In the early thirties, a young man named Dr. Richard Shope, also at the Rockefeller Institute, was studying rabbit tumors—in particular, a papilloma occurring in certain wild cottontail rabbits. Using the same basic technique employed by Rous, Shope extracted and filtered the papilloma tissue and injected the filtrate into domestic rabbits. Figure 2 shows the results after various periods of time.

The Shope papilloma agent cannot be recovered from tumors in the domestic rabbit; the animal can be infected with a filtrate, but the papillomas that arise generally cannot be transmitted from one domestic rabbit to another. Nevertheless, the presence of a virus is signified by the appearance of antibodies in the blood as the tumor develops.

Several other virus studies bore fruit during the thirties. In 1934, Dr. Balduin Lucké at the University of Pennsylvania described the transmission by a cell-free extract of kidney tumors in the leopard frog.

At the Roscoe B. Jackson Memorial Laboratory, in Bar Harbor, Maine, a geneticist, Dr. John Bittner, and others were working with inbred mouse strains. He made reciprocal crosses between high and low mammary tumor strains of mice, expecting to find approximately the same incidence of tumors in the progeny of high-strain mother-low-strain father crosses and low mother-high father crosses. But only the progeny from mothers of the high-tumor strains had the same high incidence of cancer.

In studies to determine the nature of the

Dr. Heller is director of the National Cancer Institute, National Institutes of Health, Public Health Service, Bethesda, Md. He will become president of the Memorial Sloan-Kettering Cancer Center, New York City, on July 1, 1960.

nipulates heredity like chemistry, and prepares to turn his own flimsy organism into whatever fantastic and brilliant and powerful form he most desires. The whole future is open-ended, waiting for us. This is not a time of philosophical decay but a time of birth. In the midst of our worry and fear, man reasoning, man the

creator, is about to be born. The old philosophies will burst off and blow away, unable to contain so fierce a fire. From now on, in every century, man will look back and say, this was the one.

When we speak of the sweep and excitement of science, we are speaking of the cradle of man.

Figure 3. Autopsy of mouse inoculated when newborn with polyoma virus

trate by carrying it in tissue culture. When newborn mice were injected with this filtrate, the results were remarkable (fig. 3). Not only did the mice develop primary parotid tumors, but 22 other types of tumors as well, including tumors of the thymus, adrenal glands, and mammary glands. The agent was thus named "polyoma virus." Some of the mice developed tumors within 6 weeks. Again, none developed leukemia. The investigators obtained similar results when they inoculated mice with mouse leukemia extracts incubated in tissue culture.

It is now widely believed that Gross' original material contained two viruses, the leukemia virus and the polyoma virus.

Stewart and Eddy have also shown that the polyoma virus has the unusual ability to cross animal strain and species barriers, for, although a mouse virus, it produces tumors in hamsters and rats as well.

A study conducted at the Sloan-Kettering Institute for Cancer Research in New York City about 3 years ago shed new light on the virus-tumor relationship in animal leukemia. Dr. Charlotte Friend reported her discovery of a virus that induced a leukemia-like disease in adult as well as infant mice within 2 to 3 weeks after inoculation.

Dr. Joseph Beard, the eminent virologist at Duke University, has pointed out that the studies by Friend and Gross have "firmly established the principle of virus etiology of well-known examples of mammalian leukemia." And, he adds, "There now exists a considerable body of information which is not only compatible with the hypothesis of the viral etiology of human leukemia, but which provides a substantial and reasonable background for pursuing investigations in man" ("Nature of the Viruses of Avian Myeloblastosis and Erythroblastosis" in Proceedings of the Third National Cancer Conference).

Dr. Leon Dmochowski, who with the electron microscope photographed virus-like particles in a variety of mouse and chicken tumor tissues, has conducted some interesting studies on human leukemia. In a collaborative study at the University of Texas M. D. Anderson Hospital and Tumor Institute in Houston, Dr. Dmochowski reported seeing virus-like particles in a biopsy from an enlarged cervical lymph node of a patient with acute lymphatic leukemia. He also reported that cells in the lymph nodes had undergone a number of changes similar to cell changes in affected organs of mouse leukemia and chicken lymphoma-

Figure 1. Sarcoma in the wing of a chicken 10 days after inoculation of the most potent Rous sarcoma virus preparation currently available

mother's influence, Bittner foster-nursed mice from high-tumor strains with mothers of low-tumor strains. The foster-nursed mice were relatively or entirely free of cancer, and so were their descendants for generations. In later studies, the reverse was also shown to be true. It was also found that a low-tumor strain mouse had to receive milk from a high-tumor strain foster nurse within about 10 days of birth, if it was to develop cancer. Thus was discovered the Bittner milk agent, now accepted as a virus.

Research in the Fifties

It was a long time before the studies conducted by the early pioneers of virus-cancer research were generally considered to be anything but isolated laboratory curiosities. Other paths of cancer research appeared vastly more promising than virology. In the last decade, however, a number of investigators have become interested in virus-cancer research, and have produced an impressive amount of information about animal tumor viruses and the fundamental nature of viruses and cell components.

The beginning of this new, active period is marked by a study by Dr. Ludwik Gross of the Bronx Veterans Administration Hospital who in 1951 successfully transmitted mouse leukemia with filtered extracts by injecting newborn

mice of a susceptible strain. His best results were obtained when he inoculated mice no more than 16 hours old. Gross also reported an unexpected result—some of the inoculated mice developed tumors of the parotid, a salivary gland, and miscellaneous other types. Many of these tumors rarely, if ever, occur spontaneously in uninoculated mice of this strain.

At the National Cancer Institute, Dr. Sarah Stewart attempted to reproduce Gross' results. But, although she used the same method, none of the mice she inoculated got leukemia. They developed primarily parotid gland tumors instead.

Teaming with Dr. Bernice Eddy, also at the National Institutes of Health, Dr. Stewart increased the potency of the parotid tumor fil-

Figure 2. (a) Papilloma on the inner left thigh of a wild rabbit (under the microscope these growths resemble extremely keratinized warts), (b) result of inoculation of domestic rabbit with filtrate of the papilloma tissue after 23 days, (c) after 52 days, and (d) after 118 days

training of biologists, zoologists, and chemists in the basic medical sciences related to virus-cancer research; (c) improvement of sources and distribution among laboratories of living host and viral materials; and (d) expanded financial support to include large-scale interdisciplinary explorations over long periods of time. These are excellent suggestions, and most of them have already been acted upon.

Additional conferences were held in November 1959 and in March 1960 to further explore the problems of research on viruses and human cancer. These meetings were attended by many of the Nation's leading virologists.

Establishing the role of viruses in human cancer might seem a simple matter of finding virus in malignant tissue and then demonstrating that it caused the disease. However, there is a fundamental difficulty here: at the present time we have no way to demonstrate the carcinogenic effect of viruses on humans. We must, therefore, develop laboratory techniques that will attack the problem indirectly.

A key tool in the development of such techniques will probably be tissue culture. The number of laboratories where human cells are being grown in tissue culture has greatly increased in recent years, thus facilitating the search for and study of viruses in human tissue. Research of this nature is making wider use of techniques such as treatment with X-ray or cortisone that permit human tissue to grow in experimental animals.

Other fundamental studies are equipping us with knowledge of the relationship between the host animal and the virus. Dr. Ray Bryan at the National Cancer Institute has conducted some revealing studies on the Rous sarcoma virus in chickens. He has shown that there is a quantitative relationship between the amount of virus inoculated and certain biological properties of the tumor such as size, length of time before the tumor develops, and length of time before it kills the animal. In other words, Bryan's work makes it possible to refute the old argument that a tumor cannot have been caused by a virus if the virus cannot be extracted.

One of the principal questions that must be answered is, how do viruses enter a cell and make it cancerous? For many scientists, studies on nucleic acids offer the most promise

in this area. In cells the nucleic acid DNA is localized in the chromosomes, which carry the genetic information of cells and determine their form and function. Cells also contain another form of nucleic acid, RNA, most of which is in the cytoplasm.

Viruses are known to consist largely of nucleic acid, either RNA or DNA, and protein. But until fairly recently it was not known whether nucleic acid alone could be responsible for virus activity. Then, almost simultaneously, Dr. Heinz Fraenkel-Conrat at the Berkeley Virus Laboratory and Dr. A. Gierer and Dr. G. Schramm in Germany found that the RNA of the tobacco mosaic virus showed infectious activity.

This work pointed up the vital role of nucleic acid in virus activity, and of course, the possible role of nucleic acid in cancer.

In January 1960, scientists at Sloan-Kettering and the National Institutes of Health reported that DNA has been isolated from the polyoma virus discovered by Stewart and Eddy. Cancer was produced in laboratory animals by inoculating them with tissue culture fluids in which the isolated viral DNA was carried. This strongly indicates that DNA can enter a living cell and change the DNA of the cell to make it cancerous.

Such work has breathtaking implications, and it acts as a powerful stimulus to the scientific imagination. Studies on bacteria and bacterial viruses have shown that genetic material, and thereby hereditary traits, can be transferred by a virus from cell to cell, by a process known as transduction. This transfer might cause an abnormal, malignant change in the cell. Or, a viral nucleic acid might shed its protein coat and enter a cell, become incorporated into the genetic structure of the cell, and modify it so that the cell begins to reproduce abnormally. Bacteria studies also support the concept that latent viral nucleic acid in a cell might be activated by chemical or physical agents, and thus initiate malignant growth.

These possibilities and many others constitute a broad challenge to the scientific community as a whole. Intense, collaborative efforts in many disciplines, genetics, cellular biology, chemistry, immunology, to cite just a few, are needed. The National Cancer Institute is en-

Figure 4. Mice inoculated with the Moloney virus center at 64 days of age, and right at 48 days. Left, a control C strain mouse

tosis. Visceral lymphomatosis is a common malignancy of chickens, known to be caused by a virus.

A year ago, one of our scientists at the National Cancer Institute reported a discovery that is, I believe, a real landmark in virus-cancer research. It is a fascinating story, beginning with Dr. John Moloney's studies of the properties of Sarcoma 37, an experimental mouse tumor. In the course of his investigation Dr. Moloney prepared a cell-free extract of the tumor and injected it into healthy mice. The result was quite unexpected. Within 8 months, the animals developed a type of leukemia that is indistinguishable from spontaneous leukemia in mice.

Following this lead, Moloney prepared extracts from leukemic tissue of the mice that first developed the disease, and injected these extracts into mice. By repeating this process several times, he obtained an extract so virulent that it caused leukemia within 10 weeks in 100 percent of the mice injected on the first day of life.

The leukemia agent is a virus, and the electron microscope has revealed particles that may be the virus. Unlike other mouse leukemia viruses, the Moloney virus causes the disease in several different strains. It is also active

against adult as well as newborn animals. None of the mice inoculated with the virus has developed any form of cancer except leukemia (fig. 4).

Along with the numerous reports of new virus-caused animal tumors, there have been many discoveries, often seemingly unrelated, in research on virus and cell constituents, their modes of behavior, and other characteristics. Recently we have come to see that all these results are very likely pieces of the same large and intricate puzzle.

Avenues of Research

This realization has been greatly responsible for the acceleration and vitality of virus-cancer research today. At the same time, the present phase of research in this field presents a number of problems and obstacles that demand wise and careful attention. With this need in mind, 15 distinguished scientists met at the National Institutes of Health in September 1958 to explore new approaches in virology and other sciences that might lead to major advances in human cancer. The group made four proposals: (a) basic study of viruses and animals, using electron microscopy and available animal tumors as models; (b) greater emphasis on

Experiment in Enthusiasm

DURWARD L. BLAKEY, M.D., M.P.H., RAYMOND HOFSTRA, M.D., M.P.H.,
ESTHER GILBERTSON, R.N., M.A., and JEWELL G. WYMAN, M.A.

SEVEN years ago there were 1,712 unhospitalized people in Mississippi with known active tuberculosis, 90 percent of whom were not receiving any sort of care; and there were 783 beds for tuberculosis patients, 777 of them occupied. New cases were being discovered every day. Four years later this backlog of cases had been cleared up, and by 1956 nearly 85 percent of the newly reported cases were being treated. How was this done?

"By building more tuberculosis hospital facilities," probably would be the answer of people familiar with tuberculosis control and the recommendations for hospitalization.

But there was one big difficulty. Among the 48 States in the Union at that time, Mississippi ranked 48th in both per capita and spendable family income. Obviously, this solution was out.

Although there were in existence drugs that were successful in treating tuberculosis, their cost and difficulty of administration made any sort of mass approach impractical. Then isoniazid came along and a successful formula was found: isoniazid, in combination with other drugs, and enthusiasm, administered in equal parts.

With this formula, the Mississippi State Board of Health made a new approach to the

problem. A statewide outpatient drug therapy program was started for the large number of patients with active tuberculosis who could not be hospitalized. The organization of the State health department as well as the new drugs made such a "home treatment" program practical. Health departments in each county had X-ray facilities, and State laboratory services were available. The county health departments were supervised by the State board of health so that there was uniform administration, as well as comparable treatment. The State sanatorium was also under the direction of the board of health, making the coordination of home care with hospitalization easier. It goes without saying that no undertaking of such proportions could have succeeded without the wholehearted support of the workers in the county health departments and the cooperation of private physicians throughout the State.

The objectives of this program were simple: to protect the health of the community by reducing the sources of infection and to improve the health of patients through treatment. The program was not intended to replace other forms of care, and hospitalization was still recommended whenever practical. Both patients with active pulmonary disease and with primary tuberculosis were to receive drug therapy. After the program got underway, patients discharged from hospitals with recommendations for therapy, regardless of type of discharge, were also included.

The local health departments had the responsibility for making the program work. Whenever possible, treatment was to be provided either by or under the direction of the private physician of the patient's choice. How-

Dr. Blakey is director of preventable disease control, Mississippi State Board of Health. The other authors are with the Bureau of State Services of the Public Health Service: Dr. Hofstra as chief of Program Services, Chronic Disease Branch; Miss Gilbertson as public health nursing consultant, and Miss Wyman as public health adviser, Tuberculosis Branch.

couraging such activities through a greatly expanded program of grant support for virus-cancer research. Some of the investigators participating in this program are virus experts entering the cancer field for the first time. Emphasis is on the long-term support of the scientist himself, as opposed to support of a specific project, and support of some of our grantees in this field has been recommended for periods up to 10 years. I believe that these practices, which were recommended by our advisers, will help to insure the most productive work possible in virus-cancer research.

If viruses do cause cancer in man, and if these viruses are isolated, what then? How will we apply our knowledge to help save lives?

Prevention

Naturally, prevention is what we look to as an end result of all cancer research. There has been some success in developing vaccines against virus-caused cancer in animals. Stewart and Eddy have devised a procedure that immunizes hamsters against polyoma virus. Friend has developed a formalin-killed vaccine that protects mice challenged with live leukemia virus. And successful vaccines against visceral lymphomatosis in chickens have been developed by Dr. Ben Burmester of the Department of Agriculture's Poultry Research Laboratory in Michigan. On the other hand, attempts to detect antibodies against the Moloney virus have been unsuccessful, and have therefore hindered work on the development of a vaccine from this virus. This illustrates an important point: the isolation and identification of a cancer-producing virus may not lead to the speedy development of a vaccine.

Some day, it may be possible to produce a vaccine that will prevent cancer from developing in man. It might, of course, take years to determine its effectiveness, unless a vaccine for acute leukemia were developed. In that case, the effect of a vaccine given to babies would soon be obvious, since acute leukemia most often strikes young children.

If human cancer is a virus disease, another approach might be the use of drugs designed to destroy the virus either before it induced

cancer or very early in the course of the disease. Laboratory studies of a virus that infects bacteria have shown that selective action by such drugs is possible. The virus studied induces the formation of a particular enzyme necessary for the reproduction of the virus within the cell. A powerful anticancer agent, 5-fluorouracil deoxyriboside, will seek out this enzyme, which is only in the bacteria infected by virus, combine with it, and thus block the reproduction process.

Some intriguing studies of cancer treatment in humans have shown that infection of cancer cells with certain viruses destroys some of the cells. The effect is temporary, since the patient soon develops antibodies against the virus. In further studies, attempts are being made to inhibit the host's production of antibodies against these viruses, to develop methods of reaching the cancer with sufficiently powerful doses before antibodies develop, and to produce tumor-destroying properties in other human viruses.

Virus-cancer research has come a long way in the past 50 years. And the efforts of dedicated scientists in countries all over the world assure us that our knowledge of this complex field will steadily increase. This is indeed an era in which we are continually having to re-evaluate and readjust our concepts. It is difficult to imagine what new findings may be just beyond today's horizon. But I am sure it is no mere dream that research on viruses and cancer may eventually give us valuable new knowledge and skill that will help to prevent or arrest the development of many human cancers.

have active tuberculosis in 1953 were treated under the program, nor to what extent cases newly reported in the following 2 years participated. However, 3,055 patients were taken care of during the 4½-year period between the beginning of the program and the 1957 study. If what happened in 1956 is any indication, and it is felt to be a good one, then most of the people who needed treatment got it. In that year nearly two-thirds of the newly reported active cases began home treatment, and another 22 percent were handled by private physicians and hospitals. Since about 5 percent of the new cases that year were reported at the time of or after death, only about 15 percent had no treatment or treatment was unknown.

Fifty-four percent of all the patients treated during the 4½ years had far-advanced disease when starting home therapy, and another 29 percent were in the moderately advanced stage. A substantial portion of the patients of working age (27 percent) were working either full time or part time when they joined the program. The patients were grouped in the following ways:

Characteristic	Percent
White	47
Nonwhite	53
Male	59
Female	41
25-64 years of age	71
All other ages	29

About one-fourth of the patients treated were discharged from the hospital to start home treatment and were not subsequently hospitalized. For obvious reasons, the medical characteristics of this group were quite different from those of the group who entered without hospitalization, both at the beginning of home treatment and at the time of the study.

Nearly 90 percent of the people who started treatment without hospitalization had active tuberculosis, and 60 percent had positive sputum. Among those who started treatment after leaving the hospital, 46 percent were active, 42 percent arrested, and 80 percent had negative sputum.

Reasons why patients stopped treatment during the 4½ years from the beginning of the

Figure 1. Distribution of patients at the end of successive years of treatment with drugs in Mississippi, 1953-56

NOTE: Discharged with medical consent includes patients who transferred to hospital, moved, or changed supervision.

program to the time of the study are given below:

	Program group (percent)	Hospital discharge group (percent)
Medical consent	29	63
Transferred to hospital	37	0
Moved or changed supervision	11	16
Refused or lost	14	17
Died	9	4
Total	100	100

Since the patients who had some hospitalization were in better condition when they started home treatment, it is not surprising that 63 percent of this group were discharged with medical consent as no longer needing treatment. Only 29 percent of those who entered the program without prior care were so discharged. On the other hand, the fact that more than one-third of the latter group were hospitalized eventually indicates that ambulatory treatment in many cases cannot be expected to be an adequate substitute for hospitalization. As far as keeping patients under treatment was concerned, whether or not a patient had had any hospitalization did not seem to matter.

The persons who started home treatment without previous hospital care did not get well

ever, if needed, the health departments provided part or all of the necessary medical, nursing, drug, laboratory, and X-ray services, as well as instruction of patients.

The original policy statement of 1953 defined dosage and treatment regimens for streptomycin, PAS, and isoniazid, with all three drugs to be given simultaneously to every patient when at all possible. The necessity of bed rest and proper nutrition was stressed to patients entering the program. In 1956, the original policy statement was revised to include recommendations for length of treatment by form and extent of disease.

Because of the financial situation in the State, the board of health was unable to provide any additional funds for drugs when the program was started, and the local health departments were given the responsibility of getting the necessary money in whatever way they could. This was done. The local tuberculosis associations and county boards of supervisors proved to be major sources of funds. Civic and religious organizations and individual citizens also contributed. In spite of this informal approach, local health department staffs feel that no patient was denied drugs or had treatment delayed for lack of them.

Starting in 1954, the State board of health was able to distribute a limited amount of drugs to local health departments in proportion to the amount of local funds used in buying drugs for totally indigent patients.

Since the health departments purchased the drugs in large quantities, they were able to obtain them at reduced cost. Thus many patients found it possible to pay for their own drugs. Whenever practical, patients were encouraged to contribute something toward the cost, even though in many cases this amounted to little more than a token gesture. It helped ease the burden on the health departments, and they believe it had a good psychological effect on the patients, encouraging them to maintain treatment.

The health departments found it necessary to schedule regular hours for taking X-rays and giving streptomycin injections. Staffing these additional clinics, instruction of patients, and maintaining continuity of treatment was accomplished chiefly by the nurses. In 1955, re-

gional consultation clinics were established by the State board of health to aid county health departments and private physicians in diagnosis and treatment. Each health department had access to expert medical consultation at least once every 3 months. These clinics also encouraged better use of both the outpatient and inpatient facilities of the State sanatorium.

Evaluation of Accomplishments

In the early years of the home treatment program, the demands on everyone were so great that there was little attempt to evaluate progress. After 4 years of operation there was a growing recognition of the need for factual information, and in 1957 the Mississippi State Board of Health and the Tuberculosis Branch of the Public Health Service began a cooperative study of the program (1). The material discussed hereafter comes chiefly from this survey.

The study showed that the home care program was successful in achieving its primary aim, protection of the health of the community by bringing the large number of patients with active tuberculosis under treatment and thereby reducing sources of infection. When the statewide plan was put into effect in 1953, 25 counties had already started home treatment for tuberculosis patients. By the end of the first year of operation, 69 counties had entered the program, 9 more joined the next year, and by the end of 1955, every county in the State was participating.

The number of patients participating in the program showed a similar increase. In 1953, 630 patients were being treated; by 1956 the total had risen to 1,820. There was no serious difficulty in persuading patients to accept or continue treatment. Sixty-three percent started treatment within 1 week after recommendations, 83 percent within 1 month, and 95 percent within 6 months. At the time of the study, 82 percent were thought to be taking their drugs regularly. Only 8 percent discontinued drug therapy for as long as 2 months, and only 15 percent refused treatment or were lost to supervision after they started home treatment.

It was not possible to determine exactly how many of the 1,712 patients who were known to

Nearly two-thirds of newly reported cases of active tuberculosis were either arrested or inactive

after two years

of combined

home treatment

and hospital care

(about one-third

were hospitalized

for a time)

Even if complete data had been available on all patients on home care, their progress still would not have received proper evaluation. The job was simply too large for the two part-time consulting physicians to handle. In 1956, for example, the cases of only 60 percent of the patients on drug therapy were reviewed by the regional consultants.

Supervision also proved to be a problem. About 25 percent of the patients who started home care were working, even though they had active disease. At the time of the study, nearly 30 percent of the patients with positive sputum were working.

A most glaring need was for treatment under more controlled conditions for the patients who failed to make satisfactory progress. A significant portion of the patients (20 percent) failed to show a conversion in their bacteriological status after 6 months or more of treatment. Furthermore, a substantial portion (27 percent) still had active disease after 2 years of treatment.

Discussion

Two years have passed since the survey and steps have been taken to correct some of these

weaknesses. In the area of administration, the program has been tightened by making the director of the division of preventable disease control, under the general direction of the executive officer of the Mississippi State Board of Health, responsible for coordination of the home treatment program with the State sanatorium.

Currently, when any change in a patient's status occurs, the information is immediately reported to all the other agencies participating in his care, thus improving considerably the continuity of treatment. In addition, new patients or patients who have failed to make satisfactory progress without hospitalization can be quickly admitted to the sanatorium by the two chest specialists.

Although it has not been possible to increase the number of cases reviewed by these consultants at field evaluation conferences, their work has been made more productive through greater selectivity in the cases to be reviewed. Guides are also being developed which will help even more in this selection.

The 1957 study revealed that a number of patients entered the home treatment program with the extent of their disease, bacteriological status, or both, unknown. Today, patients are

overnight (fig. 1). However, after 3 years, 56 percent had been discharged with medical consent.

A group of newly reported active cases was studied in an effort to determine the therapeutic effectiveness of the program. The group

Figure 2. X-ray and bacteriological examinations of patients with active tuberculosis treated with drugs in Mississippi, 1953-56

X-ray examinations at completion of specified number of months of treatment

Bacteriological examinations for patients with active disease

NOTE: Patient was said to have had an examination, if examination was made within 3 months before or after date due.

was composed of patients with no previous medical care prior to starting treatment at home. All had at least 6 months of treatment, and some were hospitalized at some time during the 2 years they were studied. After 2 years of treatment, 62 percent were either arrested or inactive, 27 percent were still active and continuing treatment, and the remainder had stopped treatment before their disease status had changed. However, the patients still being treated showed improvement. Nearly three-fourths had positive bacteriology at the beginning; after 2 years only slightly more than one-fourth still had positive sputum and the percentage of patients with negative bacteriology increased from 18 to 51 percent. The increase from 10 to 22 in the percentage of patients with unknown bacteriological status still considered to be active probably resulted from the absence of sputum after 2 years of drug treatment and the refusal of some patients to supply specimens.

Flaws

Thus far the considerable accomplishments of the program have been presented. Successful as it proved to be, however, Mississippi started a crash program to meet an emergency situation and only the most confirmed optimist would not have expected some flaws to develop. In addition to the difficulties inherent in supervising patients at home, the study also revealed weaknesses in the program itself.

First of all, 13 percent of the patients started home care with an unknown bacteriological status. The sputum test was the only method used to make this determination. At the end of 3 years of program operation, there was still a significant proportion of the patients who were not receiving bacteriological and X-ray examinations at the proper intervals. These weaknesses are reflected in figure 2.

The development of a reservoir of patients with isoniazid-resistant organisms is a hazard in a program of this type. It was decided, however, that the main objective of the program, to lessen sources of infection, was of primary importance and the careful medical supervision of the dispensing of drugs would minimize this element of risk.

Nearly two-thirds of newly reported cases of active tuberculosis were either arrested or inactive

Even if complete data had been available on all patients on home care, their progress still would not have received proper evaluation. The job was simply too large for the two part-time consulting physicians to handle. In 1956, for example, the cases of only 60 percent of the patients on drug therapy were reviewed by the regional consultants.

Supervision also proved to be a problem. About 25 percent of the patients who started home care were working, even though they had active disease. At the time of the study, nearly 30 percent of the patients with positive sputum were working.

A most glaring need was for treatment under more controlled conditions for the patients who failed to make satisfactory progress. A significant portion of the patients (20 percent) failed to show a conversion in their bacteriological status after 6 months or more of treatment. Furthermore, a substantial portion (27 percent) still had active disease after 2 years of treatment.

Discussion

Two years have passed since the survey and steps have been taken to correct some of these

weaknesses. In the area of administration, the program has been tightened by making the director of the division of preventable disease control, under the general direction of the executive officer of the Mississippi State Board of Health, responsible for coordination of the home treatment program with the State sanatorium.

Currently, when any change in a patient's status occurs, the information is immediately reported to all the other agencies participating in his care, thus improving considerably the continuity of treatment. In addition, new patients or patients who have failed to make satisfactory progress without hospitalization can be quickly admitted to the sanatorium by the two chest specialists.

Although it has not been possible to increase the number of cases reviewed by these consultants at field evaluation conferences, their work has been made more productive through greater selectivity in the cases to be reviewed. Guides are also being developed which will help even more in this selection.

The 1957 study revealed that a number of patients entered the home treatment program with the extent of their disease, bacteriological status, or both, unknown. Today, patients are

overnight (fig. 1). However, after 3 years, 56 percent had been discharged with medical consent.

A group of newly reported active cases was studied in an effort to determine the therapeutic effectiveness of the program. The group

Figure 2. X-ray and bacteriological examinations of patients with active tuberculosis treated with drugs in Mississippi, 1953-56

NOTE: Patient was said to have had an examination, if examination was made within 3 months before or after date due.

was composed of patients with no previous medical care prior to starting treatment at home. All had at least 6 months of treatment, and some were hospitalized at some time during the 2 years they were studied. After 2 years of treatment, 62 percent were either arrested or inactive, 27 percent were still active and continuing treatment, and the remainder had stopped treatment before their disease status had changed. However, the patients still being treated showed improvement. Nearly three-fourths had positive bacteriology at the beginning; after 2 years only slightly more than one-fourth still had positive sputum and the percentage of patients with negative bacteriology increased from 18 to 51 percent. The increase from 10 to 22 in the percentage of patients with unknown bacteriological status still considered to be active probably resulted from the absence of sputum after 2 years of drug treatment and the refusal of some patients to supply specimens.

Flaws

Thus far the considerable accomplishments of the program have been presented. Successful as it proved to be, however, Mississippi started a crash program to meet an emergency situation and only the most confirmed optimist would not have expected some flaws to develop. In addition to the difficulties inherent in supervising patients at home, the study also revealed weaknesses in the program itself.

First of all, 13 percent of the patients started home care with an unknown bacteriological status. The sputum test was the only method used to make this determination. At the end of 3 years of program operation, there was still a significant proportion of the patients who were not receiving bacteriological and X-ray examinations at the proper intervals. These weaknesses are reflected in figure 2.

The development of a reservoir of patients with isoniazid-resistant organisms is a hazard in a program of this type. It was decided, however, that the main objective of the program, to lessen sources of infection, was of primary importance and the careful medical supervision of the dispensing of drugs would minimize this element of risk.

X-Ray Protection Techniques

WALTER R. STAHL, M.D.

Oregon's radiation law, effective July 1, 1957, authorized a 2-year study of radiation exposure before promulgation of regulations and standards, discussed in a previous paper (PUBLIC HEALTH REPORTS, April 1960, pp. 331-336). The first phase was a survey of diagnostic X-ray units, which not only provided information on conditions in the State but also afforded an opportunity to offer suggestions for improvement in equipment and techniques. On the basis of inspections of several hundred units, supplemented by appropriate literature references, this paper discusses technical aspects of the survey, emphasizing methods for reducing exposure of personnel and patients. The results and their interpretation will be reported in a later paper.

THE chief of a radiological health program is continually called on to interpret the "real" biological hazard of a given exposure, the probabilities of delayed effects after certain radiation doses, reasonableness of a particular procedure from the radiological viewpoint, or significance of a given shortcoming in a specific X-ray unit. He must be able also to interpret various aspects of radiological safety practice based on, but not fully covered by, recognized standards. Good concise background material on these questions has been published (1-3).

Meeting such demands requires extensive training in the entire field of radiological health. Preferably, the chief should have a degree in medicine plus perhaps 1 year of residency in radiology or a postgraduate year in radiological health. However, with sufficient personal effort, individuals with other back-

grounds may be able to assume the responsibilities.

Suitable short-course and long-term training is offered by the Division of Radiological Health of the Public Health Service. The Atomic Energy Commission also offers courses in radiological health, but so far these have dealt primarily with the control of the potential hazards of radioisotopes.

With a well-trained chief, the other personnel in an X-ray radiation safety program can have variable backgrounds and training. Particularly valuable is prior experience as an X-ray technician. In general, however, anyone with the approximate equivalent of a bachelor of science degree can be trained to survey X-ray units. Experience in reading instruments is helpful, as is some acquaintance with medical terminology.

The program chief may train his own personnel, regardless of background, so that the proper standards are applied in fieldwork. An orientation period of about 2 to 6 months is not unusual, with frequent group training in the field on X-ray units. The staff should be supplied also with suitable reading materials, such as glossaries of medical-radiological terms, manuals of radiographic techniques (4), and the materials of the National Committee on Radiation Protection (which are published as National Bureau of Standards handbooks, available from the U.S. Government Printing Office).

Inspection Forms

Making complex value judgments concerning X-ray units in the field may be somewhat easier by the use of standard recording and recom-

no longer being started on treatment without a minimum diagnostic workup. Emphasis is being placed on the techniques of collecting sputum as well as on the need for three sputum examinations at the time of every X-ray, and the tuberculin test is being used routinely in establishing the diagnosis. In addition, the State health department no longer accepts new cases as "pulmonary tuberculosis" if the necessary reporting on extent of disease and bacteriological status is not included.

Procedures have been developed also to facilitate data collection at the end of each year on the number of patients treated, length of treatment, and clinical status. This annual evaluation provides the State board of health with the necessary information for more precise planning of its treatment program, whether in the hospital or on an ambulatory basis.

The Mississippi home treatment program was started in 1952 because it was impossible to give

hospital care to many people who needed it. Now the day is not too far distant when every newly discovered case of tuberculosis in the State can be hospitalized first, and then, once they are on the way to recovery, released to continue treatment at home. When compared to some areas of the United States, this will be regarded as nothing unique, just good tuberculosis control. But the people in Mississippi who had to face the dismaying facts in 1952 know that this accomplishment in tuberculosis control could not even be mentioned today if it were not for the State experiment in enthusiasm.

Courses in Care of Premature Infants

In the fall of 1960, the Institutes for Physicians and Nurses in the Care of Premature Infants at the New York Hospital-Cornell Medical Center, under the sponsorship of the New York State Department of Health and the Children's Bureau, will begin their 12th year of operation. These institutes are designed to meet the needs of physicians and nurses in charge of hospital premature nurseries and special premature centers, and of medical and nursing directors and consultants in State and local premature programs. The attendance at each institute is limited to six physician-nurse teams. The program for physicians is of 2 weeks duration and that for nurses of 4 weeks duration. Participants pay no tuition fee and stipends are provided to help cover expenses during attendance at the institutes. Institutes for the 1960-61 year are definitely scheduled to start on the following dates: September 19, 1960; November 28, 1960; January 23, 1961; March 13, 1961; May 8, 1961. Early application for these institutes is essential since plans are contingent on the number of applications received.

Additional information may be obtained by writing Box 143, Institutes in the Care of Premature Infants, the New York Hospital, 525 East 68th Street, New York 21, N.Y.

form is being filled out. In addition, the X-ray safety program includes lectures at meetings of practitioners of various types. The practitioners are encouraged to read the available literature, such as the booklet on X-ray protection by the American College of Radiology (5).

Specific technical problems encountered in X-ray survey work are discussed in the remainder of the paper. References to the literature, of course, represent only a sampling of the many excellent articles of recent years. It should be noted, however, that a number of these articles were written by radiologists. Their standards are not always applicable, from a practical standpoint, to general medical or dental offices.

Film Badge Monitoring

The Oregon survey revealed few instances of gross overexposure for operating personnel. This finding is consistent with reports of other surveys (6-8). Positive documentation and recording of doses by means of film badges, however, were infrequent.

The Oregon State Board of Health recommends film badge monitoring for all radiation users, although for small caseloads monitoring need not be continuous. At an approximate cost of \$1.50 per badge (for small quantities), the use of badges on two or three potentially exposed personnel for a month each year, for example, is not a major expense. Annual monitoring and special surveys whenever there is a significant change in equipment or caseload are recommended for the usual small X-ray installation.

The field personnel should be familiar with the so-called dental film monitoring method, which has been widely used, but certainly does not replace film badges. A paper clip is affixed to a plain dental film, which is carried in a pocket for a week or two and then developed. An outline of the paper clip, which appears at an estimated 25- to 40-mr exposure, is considered a positive result. Monitoring with dental films or film badges on walls, however, has little value for indicating exposure of personnel.

Pocket ionization chambers, encountered occasionally in hospitals, are useful as a supple-

ment to film badge monitoring. They tend to read low because of the softness of scattered secondary X-rays, and recording of the doses must be systematic and evaluated with caution.

For definitive advice on personnel protection, the best resource is familiarity with the standards for occupational exposure formulated by the National Committee on Radiation Protection, and published in the National Bureau of Standards Handbook No. 69. The permissible radiation is different for various parts of the body—hands, neck, lenses of the eyes, and gonads—and for the whole body, to be applied as appropriate.

The recent revision of occupational exposure limits abolished a specific weekly whole-body or gonadal exposure limit in favor of 3-month, annual, and cumulative limits. For surveillance purposes, however, the weekly maximum is 100 mr for continuing occupational exposure. The quarterly limit is 3 r and the annual limit is 12 r, but cumulative exposure is not to exceed the number of roentgens arrived at by multiplying age, less 18, by 5. Even moderately good protection leads to weekly exposures much below these limits, on the order of 25 mr per week (6,7).

Since 3 months is the shortest period for which a limit is now given and since the cumulative limit has been lowered, some film badge processors offer a double film badge: one packet to be replaced every 2 weeks and the other to be worn for 3 months. Use of this badge, which minimizes the recording of "fog" as actual exposure to radiation, seems desirable when prior exposure records are accurate and close to limits. As an alternative, wearing a single film badge for a month instead of 2 weeks would seem reasonable in most instances.

The Oregon Board of Health has not undertaken to supply film badges as part of its survey because of the expense and also because of a feeling that badges would be used more consistently if paid for by the X-ray unit owners. Further, the practitioner will have to make contact with a film badge distributor sooner or later, and the occasion of a survey is a good opportunity.

Film badges appear to be much more reliable than survey instruments for most personnel monitoring, although instruments are useful in

mendation forms. Ideally, these should be based on practical experience of several months duration. They should be concise and allow "checkoff" whenever feasible. Coding for future tabulation should be included. Suitable forms have been developed by the Division of Radiological Health, Public Health Service.

Oregon finds it practical to use such forms for on-the-spot reports of the inspections. They can be filled out in carbon duplicate, with a ballpoint pen or typewriter, the original given to the practitioner and the carbon copy retained for the office file. Although it might be charged that such reports are not written by experts, we believe that the advantages outweigh this disadvantage. First, they permit suggestions and recommendations to be given immediately to the practitioner. Second, the radiation expert back in the office usually does not have time to go over the field reports in sufficient detail to insure that his judgment of the situation will be better than that of the person on the spot. Third, writing of reports in the office cuts down efficiency of the fieldwork. Sound training in radiation principles for the fieldworkers and the use of standard forms with checkoff items prepared by an expert are key factors in this process.

The use of checkoff forms not only saves much time but also permits more detailed and uniform recommendations. Writing complete recommendations on any given X-ray unit could be an extensive undertaking. Merely putting down that "adequate coning should be provided," for instance, is almost worthless from the practical viewpoint. Details are needed on how to choose cones, the possible use of an adjustable cone, and so on. The use of a checkoff recommendation sheet does not, of course, replace individual verbal explanations on each important item during the office visit. Also, space may be used on the form for items not covered in the printed schedule. A face sheet summarizing the major inadequacies noted, degree of cooperation, and need for a revisit is useful.

The Approach

Before fieldwork is begun, letters to X-ray machine owners describing the program and,

preferably, expressing the endorsement of the appropriate professional society are useful. This step was taken in Oregon, and each user, not his secretary or nurse, was also called on the telephone and asked for a specific appointment. Time was taken to explain concisely the goals of the program, always with the attitude that the practitioner is a professional person who wishes to fulfill his responsibility in regard to radiation hazards. Our experience demonstrated that, when approached in this manner, the vast majority of practitioners will agree to a review of their X-ray units.

Endorsement of the program by the medical leaders in the community is important in obtaining active cooperation of the practitioners. The policy in Oregon has been to visit first the radiologists and larger hospitals. Grapevine information about the X-ray surveys is always widespread and can be helpful or harmful.

If possible, appointments for visits should be scheduled several days in advance to allow flexibility in regard to crowded practice hours, afternoons off, or prior commitments. A field staff of four needs perhaps half a day in a community for, say, 12 to 16 surveys. Using forms, we have found it possible to complete an inspection and report in an hour.

The typical medical or dental practitioner or veterinarian has had little formal training in taking and processing X-rays. Usually he has acquired his knowledge through experience, based perhaps on instructions supplied by X-ray distributors. Such instructions may or may not consider protection from radiation. X-ray technicians vary greatly in training and experience. Registered technicians usually have had hospital radiology department training and understand their work quite well, but even they should not be expected to know, for example, the implications of underdevelopment of films or increased kilovoltage in relation to exposure. The usual technician is office-trained by the physician and X-ray distributor, and many of them rely on prepared charts of exposure without understanding basic principles.

We have prepared a clearly written statement of the essentials of radiological protection which is left with each practitioner (in addition to the checked recommendation form), and explanations are provided while the standard

Since radiographic exposures occur in short pulses of comparatively high readings (in milliroentgens per hour), it is usually not practical to assess resulting hazards with a survey meter. We especially discourage any such time-consuming procedures as plotting isodose curves near a unit. Past experience allows one to judge protection with considerable accuracy, and, of course, film badges must provide the final proof. Since reports are written at once, we rely on past experience in making recommendations without waiting for the results of film badge surveys. If there is doubt as to what the film badges will show, we write several alternative recommendations with instructions on how to interpret the film badge results, and usually schedule a revisit.

During surveys of fluoroscopes, we record the dose rate through the leaded viewing screen and at waist height near the unit. Values in excess of about 20 mr per hour for the former and 1,000 mr per hour for the latter may require special attention if the workload in minutes of fluoroscopic viewing per week is sufficiently high. Most readings observed in Oregon, as well as those reported in the literature (11), have been below these values.

Dental X-ray units may pose some difficult problems in personnel protection. Because of space limitations and a desire to watch the patient during X-ray, many dentists consider protective shielding awkward. For small case-loads, not more than 10 to 20 dental X-rays a week, experience indicates that a long timer cord on the unit, allowing the technician to stand 7 to 10 feet away, may be adequate protection, provided there is a good tube head and careful use. A recent report shows that dental exposure rarely exceeds 300 mr per week even in offices with minimal or no protection (8). An adjacent thick plaster wall which usually provides an attenuation factor of 2 to 6, may serve as shielding. Much depends on the design of the X-ray unit.

For heavier workloads, we recommend installation of a shielding device. Special attention is given to making this convenient. A hinged, leaded plywood sheet may be attached to a wall, for example, or shielding may be built onto an existing partition. Few dentists today hold films in their hands during exposure, although

cases of chronic radiodermatitis have been seen as the result of such practices in the past. For dental X-ray units, as for all others, the personnel exposure should be documented, and the suggestions made should take cognizance of individual needs.

Patient Exposure Reduction

Personnel exposure and patient exposure present quite different protective demands, and the distinction should be pointed out during surveys. Since one is often called on to discuss possible hazards of radiation exposure, all individuals conducting the survey should receive instruction on such subjects as genetic damage, leukemia, skin burns, and damage to embryos during pregnancy. Many moderate, carefully documented statements on these subjects are available (3,5). The information given to practitioners and technicians must be based on sound facts if confidence in the program is to be established.

Regardless of what specific conclusions are reached regarding the hazards mentioned above, and we feel the hazards should be put into the reasonable context of the numerous health hazards encountered in everyday living, one can state without equivocation that the changes the Oregon Board of Health recommends reduce patient exposures associated with needed X-rays by some 50 to 95 percent without sacrifice of X-ray quality. If this is understood, one need not argue about the possible deleterious effects of a given exposure or make the avoidance of X-rays a prime recommendation. Any substantial likelihood of harm justifies using the necessary protection techniques if they do not interfere with the advantageous use of X-ray. The Oregon program does, of course, try to discourage unnecessary or unusually hazardous procedures, such as spinograms, shoe-fitting X-ray, well-baby fluoroscopy, routine pelvimetry in pregnant women, and routine examinations that cause heavy gonadal exposure, such as pre-employment examinations of the lower back.

Present standards for total population exposure to radiation are based on genetic considerations. In other words, genetic damage is thought to be the major limiting factor to

surveying fluoroscopes. The standard kit of instruments used by the Oregon Health Department, shown in figure 1, consists of a "cutie pie" ionization dose rate instrument and a condenser r meter. The instruments should be checked for accuracy in the energy region of soft X-rays before a final choice is made.

Personnel Protection Devices

In offices with small caseloads, special personnel protection devices may not be necessary, depending on attenuation by the tube head, design of the office, and work habits of the technician. Exposure should be documented in all instances, however. We usually suggest some sort of protective device to reassure the technician and provide legal protection for the owner, but on this question, as on others, judgment as to the hazards is a ruling factor. Rigid application of protection rules without consideration of the particular situation may lead to unnecessary difficulties.

In offices with a normal to heavy workload, a leaded barrier is recommended. It need not be expensive, since a lead sheet or lead-faced plywood can be purchased and installed by the owner (9). The field staff can easily learn where such materials are available locally, how much they cost, and how to install them. (This information should also be provided in the notes given each X-ray owner.)

Enclosed leaded cubicles are hardly ever mandatory in diagnostic work, although they are often found today in the larger hospitals. With adequate structural material in the walls, experience indicates that lead shielding in the walls of the radiographic room is needed only if there is an exceptionally heavy workload and permanent occupancy in adjacent rooms. However, lead is often needed behind the cassette holder used for chest and upright X-rays if the beam points into the waiting room or other occupied areas. Outside brick walls or distance often reduce the radiation exposure in the vicinity to small proportions. However, any possible exposure, including that in adjacent offices of the same building, should be documented.

Exposure of the practitioner himself may pose special problems. There are still some

physicians who do not wear lead aprons and gloves in fluoroscopy or who use excessively old or cracked aprons. Small cracks or holes in aprons are not usually important, but, of course, they should be avoided when feasible. A recent review by Hale (10) discusses other fluoroscope monitoring problems. X-ray work in operating rooms, especially in genitourinary surgery, may lead to exposure because the surgeon, normally in a sterile gown, is reluctant to go behind shielding, even if it is present. However, most such exposures are limited and the hazard is not large, provided the physician stays away from the primary X-ray beam. A film badge check of all operating room personnel is advised if such work is at all usual.

Since radiographic exposures occur in short pulses of comparatively high readings (in milliroentgens per hour), it is usually not practical to assess resulting hazards with a survey meter. We especially discourage any such time-consuming procedures as plotting isodose curves near a unit. Past experience allows one to judge protection with considerable accuracy, and, of course, film badges must provide the final proof. Since reports are written at once, we rely on past experience in making recommendations without waiting for the results of film badge surveys. If there is doubt as to what the film badges will show, we write several alternative recommendations with instructions on how to interpret the film badge results, and usually schedule a revisit.

During surveys of fluoroscopes, we record the dose rate through the leaded viewing screen and at waist height near the unit. Values in excess of about 20 mr per hour for the former and 1,000 mr per hour for the latter may require special attention if the workload in minutes of fluoroscopic viewing per week is sufficiently high. Most readings observed in Oregon, as well as those reported in the literature (11), have been below these values.

Dental X-ray units may pose some difficult problems in personnel protection. Because of space limitations and a desire to watch the patient during X-ray, many dentists consider protective shielding awkward. For small case-loads, not more than 10 to 20 dental X-rays a week, experience indicates that a long timer cord on the unit, allowing the technician to stand 7 to 10 feet away, may be adequate protection, provided there is a good tube head and careful use. A recent report shows that dental exposure rarely exceeds 300 mr per week even in offices with minimal or no protection (8). An adjacent thick plaster wall which usually provides an attenuation factor of 2 to 6, may serve as shielding. Much depends on the design of the X-ray unit.

For heavier workloads, we recommend installation of a shielding device. Special attention is given to making this convenient. A hinged, leaded plywood sheet may be attached to a wall, for example, or shielding may be built onto an existing partition. Few dentists today hold films in their hands during exposure, although

cases of chronic radiodermatitis have been seen as the result of such practices in the past. For dental X-ray units, as for all others, the personnel exposure should be documented, and the suggestions made should take cognizance of individual needs.

Patient Exposure Reduction

Personnel exposure and patient exposure present quite different protective demands, and the distinction should be pointed out during surveys. Since one is often called on to discuss possible hazards of radiation exposure, all individuals conducting the survey should receive instruction on such subjects as genetic damage, leukemia, skin burns, and damage to embryos during pregnancy. Many moderate, carefully documented statements on these subjects are available (3,5). The information given to practitioners and technicians must be based on sound facts if confidence in the program is to be established.

Regardless of what specific conclusions are reached regarding the hazards mentioned above, and we feel the hazards should be put into the reasonable context of the numerous health hazards encountered in everyday living, one can state without equivocation that the changes the Oregon Board of Health recommends reduce patient exposures associated with needed X-rays by some 50 to 95 percent without sacrifice of X-ray quality. If this is understood, one need not argue about the possible deleterious effects of a given exposure or make the avoidance of X-rays a prime recommendation. Any substantial likelihood of harm justifies using the necessary protection techniques if they do not interfere with the advantageous use of X-ray. The Oregon program does, of course, try to discourage unnecessary or unusually hazardous procedures, such as spino-grams, shoe-fitting X-ray, well-baby fluoroscopy, routine pelvimetry in pregnant women, and routine examinations that cause heavy gonadal exposure, such as pre-employment examinations of the lower back.

Present standards for total population exposure to radiation are based on genetic considerations. In other words, genetic damage is thought to be the major limiting factor to

the use of radiation. Exposure of parts of the body other than the gonads may present some hazard in regard to leukemia, for example, but it is not thought at present to be a major consideration in ordinary diagnostic work. An exception is exposure of the fetus during pregnancy. There is some evidence that exposures of pregnant women to radiation may lead to an increased incidence of leukemia in the offspring and also that the mammalian embryonic nervous system is sensitive to radiation (2). It seems prudent to avoid radiography involving the abdomen of pregnant women that is not urgently needed. Some obstetricians estimate that not more than 5 percent of pregnant women need an abdominal radiograph.

Coning and Local Shielding

To prevent genetic defects produced by radiation, primary attention is given to protecting gonads from the direct beam whenever possible. Coning of the X-ray beam and gonadal shielding are the two main techniques for this purpose, and both present complex problems.

In principle, "coning" of the X-ray beam can provide good gonadal protection. Various devices are in use for confining the beam, the commonest being a metal cone attached to the tube head. Frequently, a cone of a single size is used for X-raying small fields, such as the gall bladder or sinuses, but no provision is made for limiting beam size when larger fields must be exposed. Another device in use is a lead diaphragm fitted into the tube housing. Sets of such diaphragms cut to required sizes for various fields are available in some localities. Cones and diaphragms, to be effective, have to be accurately tailored to the particular X-ray head and field sizes and used appropriately. A single cone or diaphragm cannot provide adequate protection. As a minimum, two different cones are needed for 14-inch by 17-inch films at 72 inches and 36 inches, and an additional narrow cone must be used for small fields. However, the narrow cone, known as a "sinus" cone, may also happen to suffice for 14-inch by 17-inch fields at 72 inches. The surveyor must have a clear mental picture of the geometry of X-rays and needs to know how to locate the position of the anode on the tube housing

(usually indicated by a red spot). We usually carry a small slide rule to facilitate computations.

The following are examples of situations we have encountered in connection with beam collimation. Two or three cones are present but all are too large for the field sizes used. Cones are present, but the technician does not use them. The practitioner is willing to get one or two more cones, but the correct sizes are not commercially available. The practitioner is reluctant to spend some \$20 apiece for new cones. There is little use of available diaphragms, although sets of four or more may be on hand, labeled according to field size and use.

A more fundamental problem is that properly chosen cones allow little margin, and poor centering of the machine leads to cutoffs on films, producing some annoyance and a need for retakes. Although many radiologists may not object to slightly cut corners, others are unwilling to accept them, with the result that the cones are not used.

A variable aperture collimator offers a way out of this difficulty. Essentially, a variable aperture collimator is a continuously adjustable round or rectangular lead diaphragm, which can be set conveniently for any given field size and distance combination. A centering light or light beam is provided to facilitate positioning. A small model sells for about \$100, and better units up to \$450. We have recommended purchase of variable aperture collimators when it appeared that the practitioner would be interested. However, even adjustable collimators pose some difficulties. They must be precisely attached to the tube housing in order to produce a symmetrically centered field. Put on carelessly, they can also cause cutoffs, which force the technician to set them at a somewhat larger field size than indicated, to that extent decreasing their protective functions. Also, some of these collimators have a built-in extra beam size margin of 1 to 2 inches in all directions, which is probably necessary if one aligns with a central light spot. Several adjustable cones have been manufactured that project the entire field rather than one central spot. They should be very satisfactory, provided the light and X-ray beams are accurately centered with respect to each other.

The radiation-safety aspects of an ordinary P-A chest X-ray illustrates these problems further. One would hope to limit the beam sufficiently to protect the ovaries in the female. If a round metal cone is used, it must be checked first for proper size, using the diagonal measurement of the 14-inch by 17-inch film and about a 2-inch margin in each direction to give a final diameter of roughly 24 to 25 inches. In order to get an accurate field, the cone itself must be tailored to less than one-fourth inch in critical diameter. The necessary wide choice of cones is not usually available. If a circular field is used, its lowest portion will extend well down into the gonadal area of a woman, though the male gonads would be excluded. Rectangular cones (nonadjustable) are not widely available at present. If diaphragms are used (most machines are not equipped for them), the utmost precision is required in computing and cutting out the apertures. Because of lack of standardization on units of different ages and manufacturers, diaphragms must be practically tailor-made for the unit. If a variable aperture collimator is used, it must not allow excessive margins, and it must be accurately centered.

These complications are mentioned because it should be well understood by the field staff that the mere presence of one or even four cones does not assure good coning.

Accurate coning, of course, is more important in certain projections than others. For a film of the foot or ankle, almost any cone will protect the reproductive organs from the primary beam. In abdominal or lower back X-rays, it is difficult with cones alone to exclude the gonads from the beam.

Because of the practical difficulties in achieving adequate coning, we recommend gonadal shielding as a supplement to coning. Considerable overt resistance to local shielding has been encountered in the field. Some practitioners (and technicians) feel it will alarm patients. Local shielding may be a nuisance. For upright projections, as of the chest, rather cumbersome aprons or externally supported shields are sometimes necessary. A variety of gonadal shields are on the market, including leaded bivalved arrangements for the scrotum, but these involve hygienic and aesthetic considerations.

With radiography of the abdomen, the pelvis, the hips, or the lower spine, considerable care and ingenuity are needed if protection of the gonads is to be achieved by shielding. Various shaped pieces of lead are needed, for example, for protection of the ovaries during abdominal work, shielding of the scrotum or ovaries in infants being checked for congenital dislocations of the hips, or protection of the ovaries and fetal gonads during pelvimetry. Shields made of leaded glass woven material can be used but are low in lead equivalence and are expensive. Descriptions of specialized shielding devices are found in the literature (12-14), and one's imagination is the only limitation for suggesting new arrangements. For routine chest X-rays externally supported shielding is probably necessary if large round cones are used. Few X-ray users surveyed in Oregon have taken the steps necessary to curtail gonadal exposure in examinations of the critical lower trunk area. A useful technique for local shielding is the mounting of lead sheet on a larger clear plastic sheet, which can be positioned over the patient accurately and easily.

In photofluorographic (p.f.g.) work (in chest X-ray vans, for example) limitation of beam size is often more nearly satisfactory because precise diaphragms can be cut and permanently installed. We advise checking the actual field size projected with X-ray films or fluorescent materials. Usually the film-carrying hood assembly is coupled automatically to the X-ray head. Therefore, no centering problem arises, and small margins are possible, especially on the bottom edge. For photofluorographic work improved lens systems, fast screens, and fast film help to reduce the dose. The film used in p.f.g. units differs in size from ordinary X-ray film and is not necessarily available in the same range of speeds.

Limitation of beam size for dental X-ray units can be readily accomplished. Most dental units, however, have unnecessarily large beams although there is a plastic pointer on the outside, and a lead washer may even be installed inside it. Standards for dental radiography have been discussed in several articles (15-18). A 2¾-inch field diameter at the patient's jaw is advised. A 16-inch tube-to-skin distance is preferable to reduce parallax errors, but 8

inches is much more commonly used. Restriction of beam size is easily achieved by inserting a heavy lead "washer" inside the plastic pointer cone, of a size calculated to produce the recommended field diameter. Such washers, together with filters, are becoming widely available commercially, or they can be fabricated at minimal expense. We do not feel additional local shielding is indicated for general dental work.

Added Filtration

Another step that reduces patient exposure is the insertion of an aluminum filter into the X-ray beam (19). The filter cuts out the soft component of the X-ray beam, which otherwise would irradiate the soft tissues closer to the X-ray tube but would not contribute significantly to the actual X-ray image on the film. Current standards require a total filtration of 2.5 mm. of aluminum equivalent on radiographic units. Most X-ray tubes have an inherent filtration of about 0.5 mm., and therefore only 2 mm. of aluminum need be added. Some tubes have a substantially higher inherent filtration, up to 1.5 mm. We use a table listing inherent filtration for various machines, but when in doubt the assumption of 0.5 mm. is unlikely to cause difficulty. Provided a unit is used at kilovoltages higher than about 70, no change in exposure is required on insertion of 2 mm. of added filter, even where none was used before. At lower kilovoltages some small increase in milliamperage and time of exposure may be necessary. Many dental units operate at 55 to 65 kv. and with these the addition of 2 mm. of aluminum may cut down output to a level where exposure time becomes excessive. The current NCRP recommendations for dental machines call for total filtration equivalent to 1.5 mm. of aluminum. Most new units include the required permanent filters.

Film and Film Development

Film, film development, and film cassettes are comparatively simple components of radiological control. The usual X-ray film cassette contains two intensifying screens, one on each side of the X-ray film. Only when very fine detail is required (as in certain bones) should

film be used without such screens. Therefore, the effective exposure speed depends both on the film emulsion and on the cassette screens.

In recent years films have been substantially improved and several excellent fast films are on the market. The price is perhaps 10 percent more than for standard-speed film, but this should not deter their use. The fastest films may show slightly less detail, and radiologists may not find them entirely satisfactory for critical work. However, they are adequate for many purposes and can be expected to decrease patient exposure by 30 to 40 percent.

Cassette screens have also been improved. A pair of 14-inch by 17-inch cassette screens cost about \$30, in part because of the high standards of uniformity that are needed to prevent the production of spurious shadows on the films. Replacement of screens in all 6 to 10 cassettes used in an office is therefore expensive. Installation of fast screens in only one cassette is possible in a small office, but then two different exposure techniques have to be used. The reduction of patient exposure with newer screens is about 30 percent. An optimum combination of screen and film promises even greater reductions, and specifically matched sets will doubtless become available soon.

Experience in the Oregon survey has revealed that a majority of X-ray films are not properly processed. In order to utilize the full speed of the emulsion the film must be fully developed, which means 5 minutes at 68° F. Some film manufacturers offer charts giving times for "standard" development and "full" development. There appears little question that 5 minutes can and should be allocated to developing the film, even in an emergency. However, as with any photographic emulsion, the temperature of the developer is a critical factor in the chemical process. Full development may be obtained at 75° F. in less than 3 minutes, but with some increase in grain size and fogging. Most smaller offices have no thermostatic baths, and many technicians control developer temperature by trial and error, using surrounding sink water with fair results. Others do not watch the temperature at all and control density by inspection, which is not desirable. Small electrical bath thermostats are not expensive

and ought to be recommended in practically all offices.

To produce a satisfactory film with a development time of only $2\frac{1}{2}$ to 3 minutes at 68° F. requires approximately a 50 percent increase in exposure. If full development, fast film, and other innovations are used, exposure time and milliamperage used in the tube, or both of these, may be decreased. Usually a multiplication factor for the combined changes can be established by trial and error for some representative exposure and then applied "across the board." It is possible at times simply to decrease exposure while obtaining good results, because X-ray film has some considerable exposure latitude.

Increasing Kilovoltage

A number of articles have appeared on the advantages of high kilovoltage in X-ray work (19-21). Simply put, the kilovoltage determines the velocity of each electron while the tube current (in milliamperes) is proportional to the number of photons per unit time. The total exposure is therefore measured in milliamperes-seconds (MAS); it is proportional to the total number of photons reaching the patient. A change in tube kilovoltage has a complex effect, since it both increases the number and energy of photons. In practice a rule of thumb is that the MAS should be halved for each increase of 10 kilovolts. The advantage of higher kilovoltage is that the resulting beam is more uniform and penetrating. This increases the ratio of useful negative image to patient exposure.

Radiologists have generally considered high kilovoltage to be above 100 kilovolts. An objection has been raised that at values of 100-120 kilovolts the films have lower contrasts and are harder to read. However, radiologists who take time to get used to the "greyer" high-kilovoltage films find them completely satisfactory and often superior in range of detail. Most units in use, however, are not designed to operate at high kilovoltage. Some units may show a scale up to 110-120 kilovolts, but are not necessarily intended for heavy usage above 100 kilovolts, unless of recent design. For instance, the conventional high-voltage cables found on most

smaller units are said to fail rapidly at levels above 100 kilovolts. On the other hand, much work today is still done in the 60-75 range, which is less than satisfactory in producing a full range of detail. We recommend the use of the 75-90 kilovoltage range for the ordinary nonhospital installation, which affords a compromise between maximum reduction of patient exposure and practical demands.

When higher kilovoltage technique is adopted, the exposure charts must be extensively modified. Since modification is a complex undertaking, it is advisable to get a ready-made high-kilovoltage chart from an X-ray distributor. This can then be adapted to the given unit by a simple proportionality factor.

The radiological surveyor needs to know which distributors have charts and to study them himself so as to provide correct advice. Changing from 65 to 85 kilovolts results in substantial reductions in entrance skin exposures (by as much as 75 percent) with somewhat lesser reductions deep in the body.

Considerable time goes into explaining why higher kilovoltages are recommended since most technicians find this contrary to what they expect. Radiologists (and hospitals) commonly use medium-high kilovoltages and time and effort expended in encouraging them to go higher may be fruitful. Since radiologists are specialists in this field, some restraint is advisable in insisting that they alter their working technique. On the other hand, many of them have not given the high-kilovoltage technique a fair trial and may be encouraged to do so.

Since most dental units operate at a low, fixed kilovoltage in the order of 55-70 kilovolts, no major change in voltage is possible unless the unit is replaced. The newest dental units are adjustable and go up to 90 kilovolts.

The installations in use by chiropractors, osteopaths, veterinarians, and others are frequently, though not necessarily, old and of low maximum kilovoltage and current output. Replacement may often be advisable. However, it should be noted that kilovoltage is only one factor among many, such as filtration and film speed, and the vast majority of units in use can be put into acceptable condition though at lower than optimum kilovoltage.

We have encountered only a small number of really obsolete machines in Oregon, such as those with exposed wiring or bivalve tube shields without a full housing. These units are hazardous with respect to electrical shock alone. The surveyor should have a general idea of what new and good used X-ray machines cost and keep these figures in mind when discussing replacement. If replacement at a future date is decided upon, the practitioner nonetheless may still need to install protective items on his current equipment, since the purchase may be put off for years.

Dose Rate Measurements

A word may be said here about taking measurements of dose rate in the direct X-ray beam. We do not routinely measure dose rate in the X-ray beam except in fluoroscopic installations for the following reasons: many instruments do not read accurately with short pulses; making a full set of measurements with a condenser r meter is much too time consuming; and, most important, such measurements are really not needed to assure protection. The X-ray film itself serves as a final dosimeter for any exposure. Therefore, if a filter is present, if the kilovoltage is adequate, and if fast film is used and processed fully, the skin exposure for a given high-quality X-ray negative can be accurately predicted. While the output of machines at a given kilovoltage and milliamperage varies greatly when there is no filtration, much less unpredictability is found if the routine protective devices are present.

Many units in the field are of the convertible type, that is, the radiographic head swings under the table and is locked into position to produce a small fluoroscopic installation. For these, much information about the fluoroscopic output is already at hand after the standard inspection. Larger installations have separate fluoroscopes which require a separate survey. Frequently it is difficult to examine adequately the fluoroscopic tube head for filtration, and we therefore routinely obtain a half-value layer measurement as well as fluoroscopic dose rate in air. The half-value layer is that thickness of a given material which reduces the beam intensity by one-half. It is convenient

Figure 2. Paraffin phantom for measuring scatter radiation and depth dose

to use a 1 millimeter thickness of aluminum (pure, not alloyed) and take measurements with two suitable (5 and 10 r capacity) condenser r chambers simultaneously. Trout and associates (19) provide charts of the effective half-value layer equivalents of X-ray beams with a given kilovoltage and total filtration. Under ordinary conditions, 2.5 mm. of total tube filtration results in an X-ray beam that is further attenuated about 25 percent by an additional added millimeter of aluminum; that is, the measured dose in air and through the standard aluminum sheet (directly on the tabletop) should not differ by more than 25 percent. It is suggested that the proper values for a given instrument, filter standard, and so on, be checked empirically when a program is set up, using hospital units with a known total filtration. Somewhat more precise half-value layer measurements can be obtained with special metal caps over a condenser r chamber (10). Inaccuracies resulting from using the

chambers directly on the table rather than in a scattering medium are not very important in routine fieldwork.

Measurements of secondary radiation, however, should preferably be made with a scattering medium in the X-ray beam. Lateral dose rate at a fluoroscopic table is at least doubled by a scattering mass as large as the human body. A block of paraffin or stack of masonite sheets will serve this purpose. Measurements of semiresearch quality can be obtained by a standard paraffin block with openings at the surface and deeper channels for measurements equivalent to various depth doses. Figure 2 illustrates such a block. Aluminum sheet for half-value layer determination can be built into the block. It is then possible to get three or four useful measurements from a single exposure quickly and efficiently. If such a "phantom" is used for radiographic as well as fluoroscopic studies, special care should be taken to avoid saturating the chambers with excessively short and intense pulses of radiation.

Another basic fact concerning measurements is that even though the X-ray beam may be sharply limited by a cone, the secondary electronic equilibrium built up in any scattering mass, including the human body, extends appreciably beyond the original limits of the beam (22). Scatter measurements in a paraffin block taken, for example, 4 inches beyond what is thought to be the actual edge of the beam will be much higher than more distant scatter measurements. This point is also of importance in connection with recommendations about local shielding. For instance, any attempt to shield the ovaries with a pair of 2-inch diameter lead sheets on a plastic sheet would probably result in only a small decrease in actual radiation exposure of the ovaries because of the electronic equilibrium conditions built up deep in the body.

Special Techniques for Fluoroscopes

The present NCRP limit on fluoroscopic dose rate at the tabletop or panel is 10 r per minute in air (23). Judging by comments from local radiologists 5 r per minute is adequate for observations, and not infrequently 1 to 3 r per

minute may be practical. Milliamperage settings to achieve these dose rates run on the order of 1.5 to 3.5; but milliamperage meters are often inaccurate and should not be relied on. To fluoroscope successfully below 5 r per minute, 15 to 20 minutes of dark adaptation is recommended; even 10 minutes improves vision materially. Unless the fluoroscopic room is completely dark, light leaks may interfere with viewing. Red goggles for dark adaptation are owned by many but used by far too few. Low-efficiency screens used with some older fluoroscopic units should be replaced.
